The deflation rate soon decreased and stopped temporarily at about 17.20 h. Deflation started again at about 18.20 h. This was the main deflation and most likely related to the magma movement to the south. The centre of the rifting segment in this event was just north of the Námafjall geothermal field (Fig. 1). Some overlap exists between this rifting segment and that rifted in the previous event on 27 April 1977, as reference lines across the rift zone that already had increased in length by 2 m extended a further 1 m on 8 September⁴.

Fig. 2 Sketch map of the Námafjall area from an aerial photograph of 9 September 1977. The location of boreholes is shown by dots. The faults shown on the map have all been active in the recent events. For location see Fig. 1.

At Námafjall the first observed sign of the rifting event was movement of faults crossing a road (Fig. 2) at about 22.40 h. Assuming that the main magma movement to the south started at 18.20 h and with the distance of 9 km from Leirhnjúkur at the centre of the caldera, the rate of horizontal movement is about 0.6 m s^{-1} . A similar velocity was derived for magma movement in the April 1977 deflation/rifting event³. The figures for vertical and horizontal movement of the magma are strikingly similar to the figures (0.6 m s^{-1}) arrived at for the maximum rate of magma ascent in the Askja eruption 1961 and the Lakagígur eruption of 1783⁵, and there are indications that the magma ascended with similar velocity during the Eldfell eruption 1973 (ref. 6, p 30).

The eruption through the borehole began about one hour later, at 23.45 h. The rate of ground deflation decreased rapidly, and at about 05.00 h on 9 September deflation had stopped and the centre of the caldera was inflating again.

The borehole eruption

The Námafjall geothermal field lies on the Krafla fault swarm 9 km south of the centre of the Krafla caldera. The five boreholes in use for steam extraction are spaced with the distance of 80–200 m (Fig. 2) and extend down to 650–1,800 m with casing extending down to 500–600 m. The deepest hole has an additional slotted liner down to the bottom at 1,800 m. The boreholes are situated in a highly faulted area and deliberately placed to intersect faults at favourable depths.

The eruption took place through borehole number 4, drilled in 1968. It is 1,138 m deep, has 7" casing down to 380 m and 5" casing down to 625 m. The diameter from 625 to the bottom is 6.25" and this part has no casing or liner. The main aquifers are reported at 638 and 1,038 m (ref. 8). The average temperature of the inflowing water is estimated at 251–256 °C (ref. 7). The total discharge of the borehole at the time of eruption is not known accurately, but from measurements in 1971⁸ and the estimated inflow temperature, the total discharge of water-steam can be estimated at 30 kg s^{-1} at about 7 bar absolute well head pressure. This assumes that the inflow is water only and

that steam is generated in the borehole during its ascent. (If the inflow is a steam-water mixture a lower value results.) The superstructure of the borehole suffered minor damage due to the eruption and the borehole continued to produce steam at a similar rate as before. Following the eruption there was a marked increase in fumarolic activity in the area around the boreholes, which later decreased markedly.

Movements on faults in the Námafjall area were first noted at about 22.40 h, when the main road through the area was cut through and became impassable. By that time the eruption that had taken place 12 km to the north was finished and further activity to the south was anticipated. It was already dark, and with the steam from the boreholes drastically affecting visibility, conditions at Námafjall were confusing.

An examination of the earthquake activity shows a southward migration from the caldera along the fault swarm. The earthquake activity reached the Námafjall area shortly before 22.00 h (ref. 9).

The description below is compiled from accounts of 10 people, each of whom saw only a part of the event.

The whole event lasted between 15–25 min. It can be divided into three stages. The first phase was best observed from the main road about 400 m south of borehole 4. At approximately 23.45 h an explosion in the borehole field was heard and a thin incandescent column, about 15–25 m in height, was seen. The column widened slightly upwards and sparks and cinders were continuously shot from it. This phase of the eruption, accompanied by a continuous roar, lasted no longer than 1 min.

During the second phase, lasting the next 10–20 min, there was little or no activity at the eruption site. Occasional red flashes may have occurred during the latter part of this phase, according to some of the observers, but could also belong to the final phase.

The final phase consisted of a series of very rapid explosions or shots of glowing scoria. A few groups of explosions were observed each consisting of several individual shots (Fig. 3a). The total length of the final phase is estimated at about 1 min. During this phase the exact location of the eruption was established, when it was discovered that the pipe directly above the hole conducting the steam-water mixture had been ruptured by the eruption (Fig. 3b). It is not known whether the steam-water

Fig. 3 a, The eruption through borehole 4 at Námafjall on 8 September 1977. The picture was taken just about midnight at the distance of 50–70 m. The explosion lasted about 1 s. By comparison with the tool shed on the left the height of the eruptive column is estimated at 13–15 m. Photo Hörður Vilhjálmsson. b, Borehole 4 at Námafjall, on the morning of 9 September 1977. The steam jet is emitted through the rupture in the pipe created by the volcanic eruption. The steam-water separators are housed in the shed to the left. Practically the same scale as in Fig. 3a. Photo Sigurdur Thorarinnsson.

output was cut off at any time during the eruption, but during the second phase red flashes were seen in the steam–water mixture emitted through the ruptured knee on the pipe.

The magma was apparently injected into the hole through a steeply dipping fault intersecting the borehole above the aquifer at 1,038 m and most probably below the casing at 625 m as steam production continued after repairs of the superstructure. At the surface substantial movements on faults near the borehole were observed.

Products of the eruption

The eruption produced a tiny sheet of tephra (scoria and cinders). An area about 50 m long and of 25 m maximal width was covered by continuous layer, but single grains could be traced to at least 150 m north of the borehole. The tephra was very loosely packed and unevenly distributed and thickness estimates are uncertain, especially away from the borehole. Maximum thickness was 8–10 cm at a distance of 15–20 m.

The volume of the total output is estimated at 26 m³. The density of the deposit was roughly calculated at 0.12 g m⁻³ and the total weight of the deposit at 3,100 kg. The volume of the magma erupted is therefore 1.2 m³ using 2.7 g m⁻³ as the density of the magma.

Fig. 4 The borehole scoria. From the right: a large scoria fragment (type 1) showing a chilled, crusted surface. The edges curled up when the original piece broke and show frothy glass formed from the molten interior. Fragments (type 2) formed from the interior of larger pieces, deformed to various degrees. Some show relatively little deformation while others form spindles and small spheres. Two scoria pieces with a protrusion (type 3). The bread crust part is formed by the initial chilling and the spherical protrusion later from the still molten interior.

The tephra is greyish-black in colour and coarse grained. Median (ϕ 50) grain size in a sample collected 20 m from the 'vent' is -4.2ϕ (18.4 mm). As the largest clasts break very easily, this is likely to be an underestimate. Grains smaller than 1 mm are scarce.

The clasts (Fig. 4) can be divided into three types: (1) clasts with 2–4 mm thick, cracked, black, glassy crust ('bread crust') on one side and glass froth on the other. (2) Grains made entirely of torn glass froth of various shapes and sizes. (3) Crusted clasts of various sizes and shapes, each with a neat frothy sphere protruding from one end.

There are gradations between the different types of clasts making it possible to establish how they were formed. On injection into the borehole, the magma seems to have formed

Table 1 Microprobe analysis of the products from the eruption of borehole 4 at Námafjall, 8 September 1977

Composition of the glass

lumps of various shapes and sizes. Some of the smaller lumps survived all the way to the surface where they ripped open, and small, rounded protrusions formed from the molten interior. The larger lumps seem to have broken at various depths. The incandescence of the column indicates that most of them disintegrated within the upper levels of the borehole. Clasts with glassy crust on one side were formed from the cooled exterior of the lumps, while the molten interior disintegrated into fragments of twisted glass froth.

Assuming that the bulk of the magma was injected into the hole during the two 1-min periods, the intrusion rate is about 25 kg s⁻¹, which is of the same order as the amount of steam–water production of the borehole. Using the heights between 20 and 40 m velocities between 20 and 30 m s⁻¹ are obtained. This means that if the magma was injected at 1,000 m depth it took 0.5–1 min for it to reach the surface.

Chemistry and petrology of the magma

The scoria produced in the borehole eruption is extremely vesicular and composed almost entirely of glass. There are very occasional micropheocrysts of plagioclase, olivine and augite, always less than 0.2 mm in length. Average chemical analysis of the glass and the mineral phases are given in Table 1. The minerals seem to be in equilibrium with the liquid at the time of cooling¹⁰.

Temperature estimates at the time of chilling give 1,153 °C from the olivine–glass composition¹¹ and, 1,158 °C for the plagioclase–glass composition¹².

The chemical composition of the borehole products differs significantly from that erupted a few hours earlier 12 km to the north, but has similar composition as the lavas erupted at the beginning of the rifting on 20 December 1975¹⁰.

Thrombin-stimulated cell division involves proteolysis of its cell surface receptor

Kevin C. Glenn & Dennis D. Cunningham

Department of Microbiology, College of Medicine, University of California, Irvine, California 92717

A cell-surface component of molecular weight 43,000 is cleaved by thrombin on cells that divide after thrombin treatment, but is not cleaved on cells that are unresponsive to its mitogenic action. Studies with a photoreactive derivative of thrombin showed that its cell surface receptor has a molecular weight of 43,000. This indicates that thrombin must cleave its receptor to stimulate cell division.

STUDIES on the mechanism of the mitogenic action of thrombin have been facilitated by its ability to bring about cell division in serum-free cultures of non-dividing chick embryo (CE), mouse embryo (ME) or human foreskin (HF) cells¹⁻³. This allows experiments to be conducted in chemically defined culture conditions. Also, thrombin possesses a well characterized enzymatic activity which is necessary for stimulation of cell division^{2,4}. This makes it feasible to look for specific biochemical events that it must produce so as to bring about cell proliferation.

The first step was to establish the cellular site of thrombin action. Although thrombin is internalised by CE cells in mitogenic conditions^{5,6}, we recently demonstrated that internalisation is not necessary and that its action at the cell surface is sufficient to cause CE cells to divide⁷. This led us to examine the cell surface for events that are involved in thrombin-stimulated cell division. One such event is the binding of ¹²⁵I-thrombin to a specific cell surface receptor⁸. Scatchard analysis of the binding data to ME cells indicated a single class of high affinity receptors. It seems that thrombin must bind to its receptor to cause cell division, as small amounts of serum inhibited both the binding of thrombin to its receptor and its ability to stimulate cell division without reducing its proteolytic activity or its nonspecific association with the cells⁸.

In the present study, we radiolabelled the thrombin receptor and obtained evidence that thrombin must cleave it to stimulate cell division. The receptor was labelled using a photoreactive cross-linking derivative of ¹²⁵I-thrombin. The amount of cross-linked complex formed was proportional to the amount of specific binding, indicating that the labelled component was the cell surface receptor for thrombin. The molecular weight of the receptor was 43,000, equal to that of a cell surface component which other experiments indicated thrombin must cleave to stimulate cell division. In those experiments, we labelled cell surface proteins with lactoperoxidase and ¹²⁵I⁻ and found that a 43,000-dalton cell surface component (43 K) was present on CE cells that were responsive to the mitogenic action of thrombin and also on four separately isolated populations of CE cells that did not divide after thrombin treatment. However, 43 K was cleaved by thrombin only on the responsive cells; it was thrombin resistant on the four unresponsive populations. Thus, cleavage of 43 K by thrombin seems to be necessary for thrombin-stimulated cell division. These separate approaches suggest that a 43,000-dalton cell surface protein initiates a mitogenic signal by binding thrombin and undergoing thrombin-mediated proteolysis.

CE cells that are unresponsive to the mitogenic action of thrombin

To determine the events which cause thrombin-stimulated cell division, it was important to compare the effects of thrombin on both cells that divide and those that do not divide after thrombin treatment. An event which occurs in the responsive but not the unresponsive cells can be further studied as a possible necessary step in thrombin mitogenesis. The procedure for obtaining unresponsive cells was based on our finding that during serial subculture of CE cells, they lose virtually all of their response to the mitogenic action of thrombin or trypsin, but retain responsiveness to serum³. By the 25th population doubling, we found in four separate isolates a loss of about 80% or 90% of the mitogenic response to thrombin or trypsin, respectively (Fig. 1). This loss was not dependent on the method used to subculture the cells during the 25 population doublings, as unresponsive population I (Fig. 1b) was subcultured using 0.01% chymotrypsin whereas unresponsive population II (Fig. 1c) was sub-

Fig. 1 Comparison of cell number increases of responsive cells with two different unresponsive cell isolates. Cultures of nondividing CE cells in serum-free medium were set up as previously described³. The indicated mitogen was added and cell number was measured 24 h (a-c) or 48 h (d) later. The data shown are means of duplicate determinations obtained with a Coulter electronic particle counter. Error bars show one standard deviation from the mean. Hatched bars, trypsin ($3 \times$ recrystallised, 247 units mg^{-1} (Worthington)) was added to $0.2 \mu\text{g ml}^{-1}$. Solid bars, highly purified human thrombin (about 3,000 NIH units mg^{-1})¹⁷ was added to $3.0 \mu\text{g ml}^{-1}$. Open bars, chicken serum (Irvine) was added to 5.0%. a, secondary CE cells; b, CE cells at population doubling 26 (passage 13) which had been subcultured using chymotrypsin (0.01%) in phosphate-buffered saline (PBS) (unresponsive population I); c and d, CE cells at population doubling 28 (passage 14) which had been subcultured using trypsin (0.05%) and EDTA (0.02%) in PBS (unresponsive population II).

Fig. 2 Analysis of cell surface of responsive cells with or without exposure to thrombin or trypsin. Cell surface proteins were labelled by lactoperoxidase-catalysed iodination with $^{125}\text{I}^-$ (ref. 9). Cell monolayers were rinsed five times with Dulbecco's PBS and incubated for 5 min at 22 °C with 6 IU ml^{-1} lactoperoxidase (Calbiochem), 6 U ml^{-1} glucose oxidase (Calbiochem), 0.5 mCi ml^{-1} carrier free $^{125}\text{I}^-$ and 10 mM glucose in Dulbecco's PBS. The cells were then rinsed five times with ice cold calcium and magnesium-free PBS and solubilised and boiled for 3 min in 0.1 M Tris-HCl (pH 6.8) containing 1.0% SDS, 1.0% 2-mercaptoethanol, 5.0% glycerol and bromophenol blue. The samples were electrophoresed using 7.5–15% linear gradient SDS-polyacrylamide slab gels¹⁰. Molecular weights were determined by electrophoresing human red blood cell membrane samples²² in slab gel lanes adjacent to the ^{125}I -labelled samples. Autoradiography was performed by exposing Kodak XR-5 X-ray film to dried Coomassie blue-stained gels. Left, autoradiograms of cell surface proteins from responsive and unresponsive (population II of Fig. 1) cells that were untreated (lanes C), treated for 24 h with 3.0 $\mu\text{g ml}^{-1}$ thrombin (lanes Th) or treated for 24 h with 0.2 $\mu\text{g ml}^{-1}$ trypsin (lanes Tr) before iodination of cell surface proteins. Right, densitometric scans of autoradiograms from responsive untreated cells (a) and from responsive thrombin-treated cells (b). The arrows indicate the position of the 43,000 MW marker.

cultured with 0.05% trypsin in 0.02% EDTA. The loss of responsiveness did not result simply from a slower response to protease stimulation, as doubling the length of exposure to thrombin or trypsin from 24 h to 48 h did not increase the amount of cell division (Fig. 1c, d). Also, the loss of responsiveness was not due to a shift in the effective mitogenic dosage of thrombin on the CE cells, as they were serially subcultured. Figure 3 shows that the cells at population doubling 25 remained unresponsive even after exposures to high thrombin concentrations.

In contrast, CE cells at population doubling 25 remained responsive to the mitogenic action of serum. Although the response was reduced if cell number was measured 24 h after serum addition, there was more than a cell doubling by 48 h (Fig. 1d). ^3H -thymidine autoradiography showed that by 48 h all of the cells had synthesised DNA, demonstrating that the cell number increase did not represent multiple divisions of only a small subpopulation of cells (unpublished results). Together, these results show that by population doubling 25, CE cells lost most of their mitogenic response to thrombin or trypsin. However, they retained a full but delayed response to the mitogenic action of serum.

Cleavage by thrombin of a 43,000-dalton cell surface component from responsive but not unresponsive CE cells

These results made it possible to look for cell surface components that were cleaved by thrombin on responsive CE cells but which were thrombin resistant or absent on the unresponsive cells. Cell surface proteins were examined on thrombin-treated and untreated cells by lactoperoxidase-catalysed iodination with $^{125}\text{I}^-$ (ref. 9) followed by SDS-polyacrylamide gel electrophoresis¹⁰ and autoradiography. We also examined trypsin-treated and untreated cells, as trypsin is a potent mitogen for CE cells^{3,11–14} and can produce cell division as a result of action at the cell surface¹⁵. Figure 2 shows that 43 K was present on responsive secondary CE cells and also on CE cells at population doubling 25 that were unresponsive to the mitogenic action of thrombin or trypsin. As shown, 43 K was removed from the responsive cells by mitogenic treatments with either thrombin or trypsin. However, in four separately isolated populations of unresponsive CE cells, 43 K was not removed by these thrombin or trypsin treatments. Figure 2 shows that this could be determined by either visual examination of autoradiograms of the gels or densitometric scans of the autoradiograms. Stimulation of division of non-dividing secondary CE cells by insulin or serum did not remove 43 K from the cell surface (unpublished results). Thus, its removal was not simply a consequence of stimulating cell proliferation. DFP (di-isopropylfluorophosphate)-inactivated thrombin is non-mitogenic⁴ and does not remove 43 K from responsive cells (unpublished results). Together, the above results indicate that cleavage of 43 K is necessary for thrombin-stimulated cell division and that its cleavage is due to thrombin rather than a cellular protease.

It was important to ensure that 43 K was not a serum protein or an intracellular component. It is unlikely to be a serum protein as the cells were extensively rinsed free of serum and placed in serum-free medium for 48 h before labelling with $^{125}\text{I}^-$.

Fig. 3 Effect of thrombin concentration on cleavage of 43 K and initiation of cell division. The main figure shows the per cent increase in cell number for responsive secondary CE cells (●) and unresponsive cell population II (○) following a 24-h exposure to the indicated concentrations of thrombin. The insets show densitometric scans of autoradiograms of ^{125}I -labelled cell surface proteins of responsive cells electrophoresed as in Fig. 2. The 30,000–60,000 molecular weight regions of the scans are shown with the position of the 43,000 molecular weight marker. Responsive CE cells were either untreated (inset a), or treated with 5.0 ng ml^{-1} thrombin (inset b) or 1.0 $\mu\text{g ml}^{-1}$ thrombin (inset c) for 24 h before labelling cell surface proteins as in Fig. 2.

Fig. 4 Effect of length of thrombin treatment on stimulation of cell division and cleavage of 43 K in responsive CE cells. The main figure shows the cell number increases after treating non-dividing cultures with $3.0 \mu\text{g ml}^{-1}$ thrombin for the indicated times, rinsing the cultures and continuing incubation in thrombin-free medium from parallel cultures. Cell number was measured 24 h after the initial exposure to thrombin. Measurements at 72 h showed that the observed low responses after short thrombin treatments were not a result of delayed increases in cell number (unpublished results). The insets show densitometric scans of 43 K as in Fig. 3. Inset a, control cells not treated with thrombin; inset b, cells were labelled after a 7-h treatment with $3.0 \mu\text{g ml}^{-1}$ thrombin; inset c, like inset b, except the cells were incubated for 3 h in thrombin-free medium following the 7-h thrombin treatment but before surface labelling.

and lactoperoxidase. More important, if it were a serum protein, it would have to be one that is sensitive to thrombin and trypsin after binding to responsive cells, but resistant to cleavage by these proteases after binding to the unresponsive cells. Also, 43 K does not seem to be an intracellular protein. It was not labelled by ^{125}I in the absence of lactoperoxidase, and it was removed by thrombin treatments as short as 1 h. Although some thrombin would be internalised by that time, it would probably be in endocytic vesicles and would not have access to cytoplasmic proteins.

Removal of 43 K from responsive cells by mitogenic but not non-mitogenic thrombin treatments

To further test the relationship between cleavage of 43 K and the stimulation of cell division by thrombin, we attempted to dissociate the two events by varying the concentration of thrombin. The condition most likely to dissociate cell division from removal of 43 K by thrombin is to expose cells to the highest concentration of thrombin which is not mitogenic. Figure 3 shows that the highest concentration of thrombin that did not produce significant cell division was 5 ng ml^{-1} . As shown in Fig. 3, inset b, this concentration did not bring about a detectable change in 43 K. However, inset c shows that a maximally mitogenic concentration of thrombin removed 43 K. Intermediate concentrations gave incomplete removal of 43 K.

Replacements of 43 K after thrombin treatment seems to prevent cell division

Figure 4 shows that maximal stimulation of CE cell division by thrombin required continued exposure during the 24-h period; shorter exposures resulted in smaller increases in cell number measured either at 24 h or 72 h. An apparent dissociation between removal of 43 K and stimulation of cell division by

thrombin is shown in Fig. 4 where a 7-h treatment with $3 \mu\text{g ml}^{-1}$ thrombin removed 43 K (inset b) but produced only a $\sim 30\%$ increase in cell number by 24 h. This suggested that cleavage of 43 K by thrombin was not sufficient to achieve maximal thrombin-stimulated cell division. However, inset c shows that 43 K was replaced in the cell membrane within 3 h if thrombin was removed after the 7-h treatment. This suggests that replacement of 43 K stops the events leading to cell division and that maximal stimulation of cell division requires continuous removal of 43 K. An alternative possibility is that thrombin releases a specific fragment of 43 K that is a positive effector, the continuous production of which is required to produce maximal cell division. By studying the effects of non-mitogenic proteases on 43 K, it might be possible to determine whether 43 K is a positive or a negative effector molecule.

Fig. 5 Labelling of the thrombin receptor with a photoreactive derivative of ^{125}I -thrombin. Details of the preparation of NAPEDE- ^{125}I -thrombin and the methods to photoaffinity label the thrombin receptor will be described elsewhere¹⁶. The general protocol for this experiment is described in the text and was based on previous studies with the epidermal growth factor receptor²³. After cross-linking the ^{125}I -thrombin to its receptor, the cells were solubilised in 1.0% SDS and 1.0% 2-mercaptoethanol at 60°C for 30 min and cellular proteins were electrophoresed in 7.5% polyacrylamide tube gels containing 0.1% SDS. The line drawing shows the radioactivity in 1.0-mm slices of the gel. The inset autoradiogram shows the radioactivity in a 7.5–15% linear gradient slab gel following electrophoresis of a similarly labelled sample. The position of 80,000 and 75,000 molecular weight marker proteins are shown for this autoradiogram.

Evidence that 43 K is the thrombin receptor

As stimulation of cell division by thrombin seems to require both binding to its receptor⁸ and cleavage of 43 K, it was important to determine the relationship, if any, between the thrombin receptor and 43 K. Indeed, a relationship was suggested by the following experiments which showed that the thrombin receptor has the same molecular weight as 43 K.

As described elsewhere¹⁶, a photoactivable cross-linking derivative of ^{125}I -thrombin was prepared by covalently linking it

to *N*-(4-azido-2-nitrophenyl)ethylenediamine (NAPDE). The NAPDE-¹²⁵I-thrombin bound to cells like ¹²⁵I-thrombin¹⁶, with 60% of the total binding to specific receptors at a ligand concentration of 50 ng ml⁻¹. We then incubated CE cells with 50 ng ml⁻¹ NAPDE-¹²⁵I-thrombin for 2 h at 22 °C, rinsed away unbound reagent, treated the cells for 5 min with UV light and solubilised and electrophoresed the cellular proteins in SDS-polyacrylamide gels. Figure 5 shows the radioactivity in the gel slices from such an experiment. Peak B co-migrated with NAPDE-¹²⁵I-thrombin that had not been reacted with the cells. Peak A represents a high molecular weight cross-linked complex. Two lines of evidence showed that this complex was formed between NAPDE-¹²⁵I-thrombin and the cell surface receptor for thrombin. First, the complex was not formed in the absence of cells; thus, it was not simply intermolecular complexes of NAPDE-¹²⁵I-thrombin. Second, addition of unlabelled thrombin caused parallel declines in the amount of specific binding and the amount of cross-linked complex formed, indicating a direct relationship between the thrombin receptor and the cross-linked cellular component (unpublished results).

We estimated that the molecular weight of the cross-linked complex was 79,000 (Fig. 5). The NAPDE-¹²⁵I-thrombin had an apparent molecular weight of 36,000. Subtracting this from the molecular weight of the complex leaves a cellular receptor of 43,000 daltons. Thus, on the basis of their apparent molecular weights, the cell surface receptor for thrombin seems to be identical to 43 K described above that was identified by labelling cell surface proteins with ¹²⁵I- and lactoperoxidase.

Other cell surface events involving thrombin

We recently found that a significant fraction of ¹²⁵I-thrombin that is specifically bound to the surface of HF cells becomes linked to the thrombin receptor by a linkage that is apparently covalent¹⁸. This occurs in the absence of a cross-linking reagent. More linkage occurs with NAPDE-¹²⁵I-thrombin, although this increment depends on the cell type (unpublished results). By studying the occurrence of the direct linkage of thrombin to its receptor in responsive and unresponsive cells, it should be possible to evaluate its role in thrombin-stimulated cell division.

The treatment of mouse splenocytes with thrombin removes a cell surface component of 45,000 daltons that was suggested to be the histocompatibility antigen¹⁹. Although its role in the stimulation of splenocytes by thrombin was not examined, it might correspond to 43 K examined here. Another cell surface component that is sensitive to thrombin is one with a molecular

weight of 205,000 (205 K) on CE cells²⁰. This component was removed by both mitogenic and non-mitogenic proteases²¹. Thus, it is not simply a negative effector molecule whose removal from the cell surface is sufficient to stimulate cell division. On the other hand, the above results are consistent with the possibility that proteolysis of 205 K by thrombin produces a specific peptide that is a positive signal in or on the cell. In our experiments, 205 K was not labelled or resolved clearly enough to allow a meaningful examination of it. In future studies, it will be important to use other techniques to label cell surface proteins and to separate them on two-dimensional gels. This should allow us to study the possible involvement of 205 K in thrombin-mediated cell division and to determine if it or other cell surface components are thrombin sensitive in responsive cells but either absent or thrombin resistant in cells that do not divide after thrombin treatment. Such an attempt seems worthwhile as the requirement for at least several hours' exposure to thrombin to produce a detectable increase in cell number might reflect the need for several perhaps interdependent cell surface interactions with thrombin to produce cell division.

We thank Dr John W. Fenton II for highly purified human thrombin¹⁷ and Tom Ho and Robyn Nishimi for assistance. This work was supported by a grant from the NCI. K.C.G. was supported by a USPHS predoctoral training grant. D.D.C. was supported by a Research Career Development Award from the NCI.

Distribution of polymorphic forms of troponin components and tropomyosin in skeletal muscle

G. K. Dhoot & S. V. Perry

Departments of Immunology and Biochemistry, University of Birmingham, PO Box 363, Birmingham, UK

Specific antibodies have been used to show that in adult skeletal muscle the slow and fast forms of the components of the troponin complex are located in type I and type II fibres respectively. α -Tropomyosin is restricted to type II cells. During development, as a result of changes in innervation and in certain diseased stages, both the slow and fast polymorphic forms of the troponin components are present in the same cell.

MYOFIBRILLAR proteins are known to exist in several different forms, and the complement of these proteins present in striated muscle depends on the activity pattern of the tissue. For example, it has long been appreciated that myosins of differing ATPase activities and light chain composition are associated with fast skeletal, slow skeletal and cardiac muscles. The differential staining for myosin ATPase at different pH values implies that different types of myosin are located in each of the main fibre types of which skeletal muscle is composed¹. Electrophoretic studies of the myosin light chain components in

samples obtained from single fibres² and investigations with fluorescent antibodies^{3,4} have now confirmed that in adult skeletal muscle the fast and slow forms of myosin exist in different cells. The situation with myosin is, however, complicated, as study of its light chain composition suggests that the fast and slow isoenzymic forms of this protein may each also exist in at least two forms. For example, the alkali light chains A1 and A2 of fast skeletal muscle myosin are both present in type II fibres²⁻⁶. Therefore, if the myosin exists as homodimers (that is, each head is identical) there will be two isoenzymic forms in each cell type and three if the heterodimer possessing different alkali light chains in each head is present in addition to the homodimers. Further, there is evidence to suggest that these forms may also possess different actin-activated ATPase activities^{7,8}.

Although there is a good correlation between the type of myosin present and the speed of contraction of skeletal muscle⁹, the characteristics of the overall response to stimulation must also depend on several other factors. One of these is the nature of the regulatory proteins of the myofibril—troponin C, troponin I, troponin T and tropomyosin. The function of these proteins is to determine the way in which the myofibrillar ATPase responds to the rise in intracellular Ca^{2+} concentration that occurs during stimulation. As judged by criteria such as amino acid composition, electrophoretic mobility, complex formation and sequence studies, troponin I^{10,11}, troponin T¹²⁻¹⁴, troponin C¹⁷⁻¹⁹ and tropomyosin^{21,22} exist in striated muscles in polymorphic forms with different properties and structure. Different forms of troponin I are present in fast skeletal, slow skeletal and cardiac muscles. Although it has not been as intensively studied as troponin I the evidence available suggests that troponin T probably also exists in different forms in each type of striated muscle. Two types of troponin C have been isolated from human skeletal muscle²³ and cardiac troponin C has been reported to differ from the form present in fast skeletal muscle¹⁹. Most adult skeletal muscles are of mixed type and contain the two forms of each of the troponin components that are characteristic for the two types of skeletal muscle. Likewise the proportions of α and β tropomyosin in skeletal muscle vary according to the speed of the muscle²². The proportions of the two forms of each protein of the regulatory system present in the whole muscle are, in general, roughly that which would be expected from the ratio of the numbers of type I and type II fibres present, but not always so²⁴.

Thus the presumptive skeletal muscle cell has the capacity to synthesise several different forms of each of the myofibrillar proteins. From the information currently available about the polypeptide compositions of actin, myosin, tropomyosin and the troponin complex of rabbit skeletal muscle, about 22 structural genes are involved in the synthesis of these proteins. At any one time, in a given cell type, only 8 genes from this pool need to be expressed to produce a single form of each of these myofibrillar proteins (see ref. 25).

Fig. 1 Distribution of fast and slow skeletal forms of troponin I in sections of adult and 2-day-old mouse muscle. Unfixed tissue sections (6 μ m thick) were stained with $\frac{1}{20}$ dilution of the antiserum and the antibody localised with sheep anti guinea pig IgG labelled with type VI horseradish peroxidase^{32,37,38}. Stained for ATPase according to the method of Padykula and Herman¹ as described by Dubowitz and Brooke³⁹. The granular appearance and distribution of the stain (also see Figs 2 and 3) is a consequence of the conditions selected to obtain optimal staining for study by optical microscopy. The distribution of granules therefore does not accurately indicate the location of the myofibrils to which the antibodies are attached. *a* To *d* are serial sections of adult and *e* and *f* serial sections of 2-day-old mouse gastrocnemius muscles. *a*, ATPase at pH 9.4; *b*, ATPase at pH 4.2; *c*, immunoperoxidase with anti-fast skeletal troponin I; *d*, immunoperoxidase with anti-slow skeletal troponin I; *e*, immunoperoxidase with anti-fast skeletal troponin I (2-day-old); *f*, immunoperoxidase with anti-slow skeletal troponin I (2-day-old); $\times 200$.

As a first approach to understanding the mechanisms that regulate the complex gene pool responsible for myofibrillar protein synthesis in skeletal muscle, we have attempted to answer the following questions: (1) Are each of the two polymorphic forms of the components of the regulatory protein system associated with a particular cell type? (2) Is there a particular association of each of the polymorphic forms of the regulatory protein, that is, are the regulatory proteins laid down as a 'kit' in a given muscle cell?

The localisation of the polymorphic forms of regulatory proteins has been determined in individual cells by staining serial cross sections of skeletal muscle by the immunoperoxidase technique with antibodies to each of the purified proteins in turn. As the polymorphic forms of troponin I, troponin T, troponin C and tropomyosin are single polypeptide chains and therefore presumably single gene products, specific antibodies prepared against each of them can be used to identify unambiguously the form of each protein present in a given cell. Such studies with the regulatory proteins therefore have advantages over similar studies with myosin, each polymorphic form of which is the product of at least three structural genes. For this reason localisation studies using antibodies prepared against the whole myosin molecule, part of the molecule or one of its polypeptide subunits may not provide unambiguous information about the nature of the whole myosin molecule in the cell. This may explain why some groups report that slow myosin is present in developing skeletal muscle^{26,27} whereas other investigators conclude that the fast skeletal myosin is the major form in this tissue (ref. 27 and N. Rubinstein, personal communication). There are still other reports suggesting that myosin present in fetal muscle differs from the fast and slow forms of adult muscle^{30,31}.

Preparation and specificities of the antibodies

The fast and slow skeletal muscle forms of troponin I were isolated from rabbit white and red skeletal muscle as described by Dhoot *et al.*³² and the corresponding polymorphs of troponin T isolated from the same sources by the methods of Perry and Cole¹³ and Margossian and Cohen³³. Troponin C was isolated from combined chicken breast and leg muscles by the method of Perry and Cole¹³. All proteins were examined for homogeneity by electrophoresis of 20–30 μ g on polyacrylamide gels in 0.1% SDS, 85 mM-Tris, 400 mM borate buffer, pH 7.0. Only preparations that migrated as a single band were used as antigens. The purity of the two forms of troponin I was confirmed by comparing the mobilities of the complexes formed by the polymorphs with rabbit fast skeletal muscle troponin C^{10,32}. Although isolated from mixed breast and leg muscles of the chicken, troponin C behaved as a single antigen and its antibody does not react with the cardiac form of the protein³⁴. Further evidence for its homogeneity is given by the fact that no heterogeneity has been observed in sequence studies of chicken skeletal troponin C prepared from the same source³⁵.

Antibodies to the different forms of each of the regulatory proteins of skeletal muscle of the rabbit were raised in guinea pigs in the manner described elsewhere for antibodies to troponin I^{24,32}. The specificities of the antibodies in all cases were established by the Ouchterlony immunodiffusion test³², by the demonstration of specific staining of isolated myofibrils and by

Fig. 2 Serial sections of human semispinalis capitis muscle stained for the troponin components and α -tropomyosin. Sections were stained by the indirect immunoperoxidase staining technique as described in the legend to Fig. 1. *a*, Fast skeletal troponin I; *b*, fast skeletal troponin T; *c*, fast skeletal troponin C; *d*, α -tropomyosin; $\times 200$.

the use of adsorption techniques involving antigen linked to Sepharose or cellulose carbonate³⁶. The specificity of each antibody was further confirmed by the staining of muscle sections using the immunoperoxidase technique³². If the antibody was specific for a single polymorphic form only one fibre type was stained (Fig. 1c, d and Fig. 2). If it also contained antibody to the other form, all cells in a section of adult skeletal muscle were stained.

Although usually specific for the polymorphic form of the protein used as antigen, the antibodies to the myofibrillar regulatory proteins are not species specific^{22,32,34}. The only exception reported to date is the antibody to rabbit β -tropomyosin raised in the guinea pig. This antiserum seemed to be specific for rabbit β -tropomyosin as judged by immunodiffusion²².

Cell types and the different forms of the troponin components and tropomyosin

Immunoperoxidase studies in muscle cross-sections showed that fast skeletal troponin I was localised in type II cells (those staining dark for myosin ATPase measured at pH 9.4 (ref. 1) and slow skeletal troponin I in type I cells (those staining dark for myosin ATPase measured after preincubation at pH 4.2 (Fig. 1a, b). This localisation was a feature of all muscles from the human, rabbit, rat, mouse, hamster, rhesus monkey and baboon that were examined³². In normal adult muscle, virtually all the cells studied appeared to contain either one or other of the two forms of skeletal troponin I. In Fig. 1c, d this distribution is illustrated for mouse gastrocnemius muscle. Only on very rare occasions were intermediate type cells seen that stained for both fast and slow forms of troponin I. In these cases the intensity of staining for each polymorphic form of skeletal troponin I was less than that observed in cells that stained for one form only.

In view of the precise and clear differentiation of adult skeletal muscle cells into two types based on the immunoperoxidase staining method for fast and slow skeletal muscle forms of troponin I, we have suggested that this procedure presents a rapid, convenient new method for typing muscle cells³².

Study of serial sections showed that the antibodies to the fast skeletal muscle forms of troponin T, troponin C and α -tropomyosin stained the same cells as those stained by fast skeletal muscle troponin I. This distribution is demonstrated with human semispinalis capitis muscle in Fig. 2, but has been observed in all muscles studied to date. As far as it could be judged from the intensity of staining observed in the immunoperoxidase test, the fast skeletal muscle forms of the components of the troponin complex and α -tropomyosin were absent from the type I cells. Slow skeletal muscle troponin T was localised in the type I cells. The specificities of the antibodies to the fast and slow forms of troponin T and the differential staining of the type I and type II cells with those antibodies is the first unambiguous demonstration that the slow and fast skeletal muscle forms of troponin T are different. Preliminary studies with antibody raised against rabbit cardiac troponin C indicate that this antibody reacts with type I cells only. In Ouchterlony diffusion tests the antibody gave a precipitin line with troponin C isolated from rabbit slow skeletal and cardiac muscles but not with fast skeletal muscle troponin C. Our results do not permit us to decide whether troponin C in the type I cells is identical with cardiac troponin C or merely cross-reacts with antibody to this protein. The primary sequences of troponin C from rabbit slow skeletal muscle and bovine cardiac muscle are very similar (J. M. Wilkinson, personal communication).

Extrapolation from the general pattern of results obtained with antibody to α -tropomyosin and the fact that all the muscles studied contain β -tropomyosin suggest that the latter polymorph is located in type I cells in mammalian muscle. Preliminary studies with antibody to β -tropomyosin indicate that this is the case (G. K. D., N. Frearson and S. V. P., unpublished

results). Our data do not yet permit us to conclude with certainty whether β -tropomyosin is absent or present in type II cells. As the results indicate that α -tropomyosin is absent, or present in such small amounts that it cannot be identified by the immunoperoxidase technique in type I cells, tropomyosin must be present as the β_2 dimer in these cells. Direct evidence for the

Fig. 3 Comparison of localisation of fast skeletal troponin I in normal and dystrophic human muscle. Sections stained for fast skeletal troponin I by the indirect immunoperoxidase technique as described in Fig. 1. *a*, Normal human quadriceps muscle; *b*, quadriceps muscle from a patient with Duchenne muscular dystrophy; $\times 200$.

existence of the β_2 form of tropomyosin in adult muscle has not previously been obtained, although it must exist in rabbit fetal muscle, the tropomyosin of which consists of 80% of the β form⁴¹. Table 1 summarises the conclusions we can make so far on the localisation of the polymorphic forms of the regulatory proteins in the two types of adult skeletal muscle.

Factors affecting the expression of genes controlling synthesis of regulatory proteins

Our studies suggest that there is a very precise association of the different polymorphic forms of the regulatory proteins in normal adult skeletal muscle. The existence of two isoenzymic forms of fast and slow myosin in type II and type I cells respectively, however, indicates that there may be more flexibility as to the form of the myosin molecule incorporated into the myofibrillar structure of a given fibre type than there is with the regulatory proteins. Such a rigid association of the different forms of the regulatory proteins in adult skeletal muscle must be an important factor in determining the contractile properties of the myofibril that are characteristic for the cell type.

The presence of a single polymorphic form of each of the regulatory proteins in a given cell type is a feature of adult muscle. This does not apply at all stages of muscle development for we have observed fast and slow forms of troponin I, troponin T and troponin C in the same cells in developing rabbit, rat and mouse leg muscles. Gauthier *et al.*²⁷ and N. Rubinstein (personal communication) have reported the fast and slow forms of myosin to be present in a single cell in developing muscle, as have Pette and Schnez⁵ in adult muscle after direct stimulation with frequencies different from that normally associated with the muscle.

In newborn animals all the cells from skeletal muscle of the leg stain for fast troponin I. A few, which are presumptive type I fibres, stain weakly for slow troponin I and as development proceeds those cells containing slow troponin I progressively stain more strongly for the slow polymorph and less strongly for the fast form (Fig. 1e, f). Finally the latter disappears completely and the cells appear as normal type I cells staining only for the slow forms of troponin I. A similar pattern of localisation is shown by the fast and slow forms of troponin T and troponin C. Thus it seems that during the late fetal and the early postnatal stages of development, the genes responsible for the fast forms of the troponin components are active in all muscle cells. Only in those cells programmed to become type I fibres are the genes responsible for the slow forms of the troponin components expressed as well. As development and specialisation progress, all but one of the genes responsible for the syntheses of the polymorphic forms of a given regulatory protein are suppressed until finally a predetermined kit of myofibrillar protein (see Table 1) is synthesised, probably under some type of control involving coordinated gene expression, possibly similar to the operon type of control observed in prokaryotes. The elucidation of the mechanisms of the control of the expression of the genes responsible for synthesis of the different forms of the myofibrillar proteins presents a fascinating problem of cell specialisation in response to innervation and activity pattern.

Thus the rigid control of the synthesis of the various polymorphic forms of the myofibrillar proteins is a feature of normal adult muscle. Any change from the normal function of the muscle caused by an alteration in the pattern of stimulation or changes induced by cross re-innervation or by regeneration as a result of disease or injury would, therefore, be expected to change the pattern of localisation of regulatory proteins and possibly also other myofibrillar proteins. It was mentioned above that fibres from the skeletal muscle of adult animals which stained for both fast and slow forms of skeletal troponin I were observed very infrequently. These cases could be explained on the basis that the muscle was not normal or that the animal had been treated in some way that could have promoted some change in its muscle. This view has been reinforced by the fact that examination of samples of muscles from patients with some known primary and secondary myopathies has usually shown that a large number of cells contain both fast and slow polymorphic forms of troponin I and troponin T. This is illustrated for troponin I in Fig. 3 which shows sections through muscle from a normal adult and a patient suffering from Duchenne muscular dystrophy. The study of the distribution of the different forms of the regulatory and probably other myofibrillar

Table 1 Distribution of polymorphic forms of the myofibrillar proteins in skeletal and cardiac muscle of mammals

SS433—a massive black hole?

SPECTROPHOTOMETRIC observations by Margon *et al.*¹ have drawn attention to some remarkable spectroscopic activity in the object Stephenson–Sanduleak 433. In addition to broad, intense Balmer, He I and He II emission lines, Margon *et al.*¹ report the presence of broad, strong anomalous emission lines which move rapidly across the spectrum. For example, their Fig. 3 shows the behaviour of two such lines (one at $\sim 6,000$ Å and the other at $\sim 7,400$ Å with mean value just redwards of $H\alpha$) on three nights in a four-day interval. The IR line moved redwards by ~ 150 Å and the red line bluewards by ~ 70 Å. If interpreted as Doppler shifts these movements imply velocity changes of $6,000 \text{ km s}^{-1}$ and $-3,500 \text{ km s}^{-1}$ respectively. We propose here that these anomalous emission lines are produced by an emitting ring of gas in a circular orbit around a central, massive black hole.

The line profile of emission from such an orbiting ring (see ref. 2) consists of two emission peaks, one on either side of the rest wavelength λ_0 , at wavelengths $\lambda_{\pm}$ corresponding roughly to $\pm V_{\text{orb}}$, the orbital velocity of the ring. That is, roughly, $\lambda_{\pm} = \lambda_0 (1 \pm V_{\text{orb}}/c)$. There is also a certain amount of emission between the two peaks, which in this case, we suggest, is masked by the underlying continuum. For SS433, however, the orbital velocity must be so high ($V_{\text{orb}}/c \approx 0.15$) that the orbit is sufficiently close to the central object that the net gravitational redshift of the orbit must also be taken into account. This has the effect of shifting the mean wavelength of the two emission peaks to the red of the rest wavelength as is indeed observed.

For a thin ring in a circular orbit at radius $R = r GM/c^2$ around a Schwarzschild black hole of mass M , the two emission peaks will be at wavelengths given roughly by

$$\lambda_{\pm} = \lambda_0 \left\{ 1 \pm \left(1 - \frac{2}{r} \right)^{-1/2} \frac{\sin i}{r^{1/2}} \right\} / \left(1 - \frac{3}{r} \right)^{1/2}$$

where i is the inclination of the ring's orbit to the line of sight³. These wavelengths are shown for $H\alpha$ and $H\beta$ in Fig. 1, for various values of r and i . Also shown are the wavelengths observed by Margon *et al.*¹, which can be fitted by a ring of given inclination whose radius steadily decreases with time. Note also that as the ring's radius decreases, we would expect the blueward peak to reverse direction, having got as far as the region around He I at $5,876$ Å, the precise value depending sensitively on the inclination (see ref. 4). At the same time the red peak from $H\beta$ appears in the same region. Evidence for such behaviour is reported by Ciatti *et al.*⁵ and by Margon *et al.*¹. Furthermore, from symmetry considerations we would expect the profiles of the emission peaks at any given time to be mirror images of each other (at least on timescales longer than the orbital time). The data presented by Margon *et al.* lend some credence to this. Although we have considered mainly the strong Balmer lines, there is evidence that other lines (such as, He I, He II) display similar behaviour.

We now consider the physical properties of the emitting region. The width of the emission peaks indicates that the thickness of the ring, ΔR , is small, say $\Delta R \leq 0.1R$. Taking $R \approx 50 GM/c^2$ (see Fig. 1) we find that for the emitting region to be large enough that its brightness temperature in the lines does not exceed $\sim 10^4$ K, we require $M \geq 3 \times 10^5 M_{\odot}$. Hence we conclude that the central object is a massive black hole. To obtain the observed (dereddened) anomalous line luminosity, we find that the particle density in the emitting region is $n_{\text{em}} \sim$

Fig. 1 The predicted wavelengths λ of the red (a) and blue (b) wings of $H\alpha$ and the red (c) wing of $H\beta$ are shown as functions of the radius of the emitting ring, r in mass units or r_s in Schwarzschild radius units, for inclination $i = 45^\circ$. The shaded region corresponds to $40^\circ \leq i \leq 50^\circ$. The filled circles and bars indicate the positions and widths of the lines observed by Margon *et al.* on 23, 24 and 26 October 1978. Thus the observations are consistent with a steadily decreasing radius. Also shown are the rest wavelengths of He I, $H\alpha$ and of the atmospheric A band.

10^{12} cm^{-3} and the total emitting mass to be $m_{\text{em}} \sim 10^{24} \text{ g}$. Note that the rate at which such a mass releases energy as it falls from $r = 28$ to $r = 22$ in a time of three days (Fig. 1) is $\sim 10^{36} \text{ erg s}^{-1}$, comparable to the dereddened anomalous emission line luminosity.

Ipser and Price⁶ have considered accretion on to massive black holes within the galaxy. They find that a hole of $\sim 3 \times 10^5 M_{\odot}$ passing through the plane of the galaxy would accrete sufficiently to radiate a total luminosity of $\approx 10^{38} \text{ erg s}^{-1}$. They also predict that, if a large part of the mass of our galaxy is in the form of such objects, the nearest such object should be at a distance of a few kpc and have a velocity of $\sim 300 \text{ km s}^{-1}$. These findings are in accord with the observations of SS433. We suggest therefore that the optical continuum radiation, broad emission lines, weak radio and X-ray emission from SS433 are produced by the accretion process.

One problem with our model is the explanation of why the emitting ring remains so narrow. The effect of viscosity on an accreting ring spreads the ring out as it accretes⁷. The emission observed may come predominantly from the densest part of the accreting ring; or we may be witnessing the accretion of a solid body of about planet size (say of mass $\sim 10^{28} \text{ g}$) as it spirals inwards because of friction within a more slowly moving accretion disk. The anomalous emission would then come from a thin ring of steadily decreasing radius in the neighbourhood of the planetoid. In this case the orbital period of $\sim 1 \text{ h}$ might be detectable.

We thank Drs A. Fabian, M. Rees, N. Sharp, C. Whyte and R. Znajek for helpful discussions.

Neutrinos from neutron stars

SEVERAL schemes to detect ultra-high energy (UHE: $\geq 10^{12}$ eV) muons and neutrinos produced by cosmic ray interactions in the atmosphere have been recently studied¹, and the applicability of the resulting designs to extraterrestrial sources is being discussed². We present here the results of a calculation to determine the flux of UHE neutrinos from galactic neutron stars and the consequent number of point sources detectable at the sensitivity threshold of the proposed deep underwater muon and neutrino detector¹ (DUMAND) array.

Pulsars, with their huge magnetic and electric fields and their ready supply of (rotational) energy, are obvious candidates as sources of UHE particles and radiation³. The Crab pulsar emits pulsed γ -rays at energies exceeding 10^{12} eV, and the neutron star in the binary X-ray system Cyg X-3 has been detected as a UHE γ -ray source modulated at its binary orbital period of 4.8 h (ref. 4). In addition, pulsars are considered to be a likely site of cosmic-ray particle acceleration, and the highly relativistic wind from young sources probably dominates the energetics of some supernova remnants.

The requirements for the production of celestial UHE neutrinos are simply a source of UHE particles, and sufficient target material to produce a significant probability that these particles will convert their energy into neutrinos by a kaon/pion-producing collision followed by the charged meson's decay. For example, to convert ~50% of its energy into neutrinos, a 10^{12} eV proton must traverse ≥ 50 g cm⁻² of material or a column density of $\sim 10^{28}$ high energy photons cm⁻² (ref. 3). The high photon densities are probably not relevant to neutron stars in a galactic setting and will not be considered further here. Table 1 lists common pulsar environments and the resulting column densities of matter encountered by a UHE proton on its journey from the neutron star's surface to Earth. In general, for single pulsars, it seems that the amount of material present is 3–5 orders of magnitude too small; even for a source on the far side of the Galaxy with a line of sight passing through several giant molecular clouds, <1% of the material needed by a proton for the deposition of half its energy in neutrinos is encountered.

Only in the case of a neutron star in a close binary system with a companion undergoing rapid mass loss does the amount of matter become significant. In systems where massive accretion disks or circumstellar shells develop, or where the neutron star actually buries itself within the envelope of its companion⁵, the

column densities can easily exceed the required 50 g cm⁻². In the estimates of neutrino fluxes derived below, we adopt a conversion efficiency $\eta_T = 10^{-1}$ for the energy available in UHE particles from neutron stars in such binaries, and $\eta_T = 10^{-4}$ for the remaining objects.

The ultimate power source for relativistic particles and radiation from neutron stars is their rotational kinetic energy. All of the radio pulsars for which measurements have been made are observed to be slowing down. Their energy loss rate $\dot{E}$ is given by

$$\dot{E} = \frac{1}{(2\pi)^2} I \nu \dot{\nu} = 4 \times 10^{46} \nu \dot{\nu} \text{ erg s}^{-1}$$

where ν and $\dot{\nu}$ are the pulsar rotation frequency and its first derivative, and the value of the star's moment of inertia I is taken to be 10^{45} g cm². The potential UHE particle luminosity (L_p) from the Crab pulsar, then, is $\sim 5 \times 10^{38}$ erg s⁻¹, while from a typical 1 Myr old source, L_p is $\sim 5 \times 10^{33}$ erg s⁻¹ (see Table 2); these numbers represent an absolute, model-independent upper limit to the energy available in UHE particles from pulsars.

Michel⁶ offers an alternative to this naive assumption of a rotational energy-to-particle conversion efficiency of unity. Working from the basic assumption that the plasma being accelerated from the neutron star's polar cap is described as space charge limited flow, he has performed a dimensionless analysis which indicates that most of the star's energy loss goes into electromagnetic fields rather than particles, regardless of the physical parameters of the source. In particular, one can estimate L_p and the average particle energy ϵ_p solely as a function of the observed energy loss rate and the charge and mass of the accelerated nuclei. The particle energies are just those required for UHE neutrino production: for the range $10^{32} \leq \dot{E} \leq 10^{39}$, we obtain 2.5×10^{12} eV $\leq \epsilon_p \leq 1.5 \times 10^{14}$ eV for iron nuclei and values a factor of 2–4 less for α particles. However, the conversion efficiency for rotational energy to particles, η_B , is typically $\leq 1\%$; we find

$$L_p = 6 \times 10^{35} (\dot{E} \times 10^{-38})^{3/4} \text{ erg s}^{-1}$$

implying a Crab pulsar particle luminosity of $L_p \sim 2.4 \times 10^{36}$ erg s⁻¹ (for iron ions) which decreases to $L_p \sim 5 \times 10^{32}$ erg s⁻¹ for a 1 Myr old source (these values are lower by a factor of ~ 4 for α particles). For those neutron stars in accreting binaries, the infalling plasma may hinder the particle acceleration mechanism and reduce the UHE particle flux still further.

Having obtained estimates of the relevant efficiencies for the energy transformation rotational kinetic $\rightarrow$ relativistic particle $\rightarrow$ UHE neutrino, we need only determine the number of active neutron stars in the Galaxy to establish limits on the number of detectable neutrino sources. X-ray catalogues^{7,8} (which are complete for the galactic sources with luminosities $\geq 10^{36}$ erg s⁻¹) list ~ 100 objects thought to contain heavily accreting neutron stars in binaries (type (a) binary of Table 1), while a review of data on X-ray transients⁹ suggests perhaps 10–50 times this number of systems may exist with lower and/or sporadic accretion rates. Many authors^{10–14} have analysed the

† Model independent upper limits.

‡ Based on the space charge limited flow (SCLF) assumption of Michel⁶.

available pulsar data and have estimated the total number of active radio pulsars in the Galaxy to be between 10⁵ and 10⁶. However, due to their monotonic decrease in energy loss rate, only the youngest of these pulsars will contribute significantly to the flux of UHE particles available for neutrino production. Although it is generally accepted that pulsar characteristic ages ($\tau = P/2\dot{P}$) are poor indicators of the true source ages^{10,11,15}, the values of τ for the two youngest objects (the pulsars associated with the Crab and Vela supernova remnants) agree well with the independent age estimates available, and most authors agree that up to about 1×10^6 y, τ may provide a reasonable chronological age. Of the ~110 sources with measured period derivatives, 25 have characteristic ages of <1 Myr^{16,17}. The numbers of these pulsars in each of several age brackets, their observed energy loss rates and the extrapolated total population of each group in the Galaxy, are shown in Table 2. The estimates for single pulsars are based on a steady-state birthrate of one source per 6 yr^{10,14}. The numbers for neutron stars in binary systems are crude estimates based on a constant (with age) fraction of 0.1% of the total population. This value is consistent with the X-ray data, but it does not include evolutionary considerations which might either selectively enhance (such as, by the production of relativistic wind-induced envelopes around young objects¹⁸) or deplete (for example, due to long evolutionary time required for the companion to reach the mass-losing stage¹⁹) the number of young objects in accreting systems.

The proposed DUMAND array¹ has a point source detection threshold of ~10² eV cm⁻² s⁻¹. The results presented in Tables 1 and 2, with our adopted efficiencies η_T and η_E , allow us to estimate the number of neutron stars that we can expect to observe at this level of sensitivity. We assume that the young pulsars enumerated in Table 2 are uniformly distributed throughout the galactic disk within a galactocentric radius of 12 kpc (this ignores the radial and Z-height dependences of the pulsar distribution¹⁰, however, this will not appreciably affect the results). Table 3 presents the neutrino luminosities for various energy loss rates and the estimated number of detectable sources based on our derivations of η_E and η_T . To typical astrophysical accuracy, we may conclude that there will be no source confusion problem for DUMAND (resolution $\leq 1^\circ$) in observing galactic neutron stars, but, with a little luck, a few detections are possible.

Note that any such source observed in the UHE neutrinos will not be invisible to all other types of detectors. These objects will produce a copious flux of γ rays, and in the case of the close binary systems, an accretion-powered X-ray source is also expected. In fact, among the 15 or so localised 100 MeV γ -ray sources in the galactic plane²⁰, five are associated with known or suspected neutron stars: four radio pulsars including the one in the Crab Nebula, and the binary X-ray source Cyg X-3. The latter two objects have already been observed by Cerenkov detectors in the UHE regime ($E_\gamma \approx 10^{12}$ eV)⁴. In the case of the radio pulsars, these high energy photons may be produced through curvature radiation or some other processes associated with the pulsar mechanism rather than through the meson decay

which would require an accompanying flux of neutrinos. However, the case of Cyg X-3 is promising. Bignami, Maraschi and Treves²¹ and others^{22,23} have suggested a model for this source involving a young neutron star embedded in the dense stellar wind of its red dwarf companion. The X-ray emission is powered not by accretion, but by interaction of the relativistic outflow (in dipole radiation, particles, and so on) from the pulsar with the plasma surrounding the system. The observed UHE γ -rays show an orbital phase distribution which peaks when the X-ray source (the neutron star) is near eclipse⁴; that is, when our line of sight passes through the maximum path length of circumstellar target material. No other similar systems have been optically identified, and it is difficult to resist the speculation that this source is one of the handful of binary neutrino sources predicted in Table 3.

We have attempted to estimate the number of neutrino point sources powered by galactic neutron stars which will be detectable with the DUMAND array. While the prospects for such observations are far from sanguine, the totally new view of the objects discussed here offered by a UHE neutrino telescope can only add to the many potentially fundamental physical insights that the study of galactic neutron stars is sure to provide.

Long chain carbon molecules and diffuse interstellar lines

THE diffuse interstellar lines, seen in the optical spectra of stars which lie behind fairly low density interstellar clouds, have remained unidentified for many years. It has recently been suggested¹ that the diffuse interstellar lines are the absorption bands of long chain carbon molecules, C_n , where n may be in the range 5–15. As one possible source for these molecules, Douglas¹ proposes that long chain hydrocarbons are synthesised in dense interstellar clouds. After cloud disruption, the hydrocarbons may lose their hydrogen atoms by photodissociation and exist as pure carbon chains. While the shortest of the chains (C_2 , C_3 , C_4) will themselves be photodissociated, Douglas¹ argues that chains beyond a certain length are stable against photodissociation and will persist in the low density clouds in which the diffuse interstellar lines are formed. As a first step in evaluating the feasibility of this route, we estimate here the abundances of chain hydrocarbon molecules which would be expected in dense interstellar clouds as a result of gas-phase chemistry alone. The rather high abundances of hydrocarbons which we predict support the identification of carbon chains as the source of the diffuse interstellar spectral features.

Rate coefficients for ion-molecule reactions leading to hydrocarbon-chain molecules with up to five carbon atoms have been measured in the laboratory^{2,3}. The most important of these measured reactions are

Further acetylene additions can occur by reactions of the form³

for $n = 2, 3, 4, \dots$

We have argued⁴ that methane, which is required if the synthetic reactions (1–5) are to proceed, should be abundant in dense clouds. We found, for a fractional ionisation of $e/n = 3 \times 10^{-8}$ (refs 5, 6), and a rate coefficient of $4 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$ for the radiative association reaction of CH_3^+ with H_2 (ref. 7), that $[CH_4]/n \approx 10^{-6}$, where $n = n(H) + 2n(H_2)$. The recent detection of methane in Orion A⁸, although not leading to a reliable column density because of non-thermal excitation, is compatible with a high methane abundance. Acetylene is produced by reaction (1a) and is destroyed by reaction (2) so that the relative abundance of acetylene is

$$C_2H_2/n \approx \frac{k_{1a}(C^+/n)(CH_4/n)}{k_2(C^+/n)}$$

where we use the notation $X/n = [X]/n$. Since $k_{1a} \approx k_2$, we find that $C_2H_2/n \approx CH_4/n \approx 10^{-6}$.

At each step in the sequence of reactions (1–8), recombination with electrons leads to neutral hydrocarbons. The destruction rate of the neutral molecule is required for a determination of its abundance. The assumption that destruction by reaction with C^+ provides an estimate of the actual destruction

rate for a complex molecule⁴. With this assumption, the equilibrium abundances of the neutral molecules are readily obtained. In view of the uncertainty in the number of hydrogen atoms ejected after recombination, we use the notation C_nH_m for the neutral molecule containing n carbon atoms. For example, C_4H_m will represent all of the likely products for the recombination of both $C_4H_3^+$ and $C_4H_2^+$, namely C_4 , C_4H , C_4H_2 and C_4H_3 .

To illustrate the method of calculation we will obtain the equilibrium abundances of C_3H_m and C_2H_m . C_3H_m is formed by reaction (2) followed by recombination, and is destroyed by reactions with C^+ (by assumption), so that

$$C_3H_m/n = \frac{k_2(C^+/n)(C_2H_2/n)}{k_{C^+}(C^+/n)}$$

where k_{C^+} is the rate coefficient of the reaction

If $k_{C^+} \approx k_2$, we find that $C_3H_m/n \approx C_2H_2/n \approx 10^{-6}$. Similarly,

$$C_3H_m/n = \frac{k_3(C_3H^+/n)(C_2H_2/n)}{k_{C^+}(C^+/n)}$$

Since C_3H^+ is formed by reaction (2) and destroyed by recombination with electrons,

$$C_3H^+/n = \frac{k_2(C^+/n)(C_2H_2/n)}{k_e(e/n)}$$

where $k_e (\approx 3 \times 10^{-7})$ is the recombination rate coefficient. Using $C_2H_2/n \approx 10^{-6}$, $k_{C^+} = 2 \times 10^{-9} \text{ cm}^3 \text{ s}^{-1}$, $e/n = 3 \times 10^{-8}$, and the measured values³ for k_2 and k_3 , we find $C_3H_m/n \approx 2 \times 10^{-7}$.

The equilibrium abundances of molecules with up to 12 carbon atoms, obtained with the assumption that reactions (6–8) have a rate coefficient of $2 \times 10^{-9} \text{ cm}^3 \text{ s}^{-1}$, are given in Table 1. It can be seen from Table 1 that the calculated abundances of C_n molecules remain quite high even for n as large as 11. By way of comparison, a fractional abundance of $10^{-9} \leq CH/n \leq 10^{-8}$ produces the strong observed interstellar lines of CH. The decline in abundance towards larger molecules is slower than might have been expected: $C_{2n+1}H_m/C_{2n+3}H_m \approx 5 \approx C_{2n}H_m/C_{2n+2}H_m$ for $n = 1, 2, 3$ and 4. The predicted ratio for hydrocarbons is close to the observed ratio for cyanopolynes of $HC_{2n}CN/HC_{2n+2}CN \approx 4$ for $n = 1, 2$ and 3 (ref. 9).

The predicted abundances of hydrocarbons with an odd number of carbon atoms are higher than the abundances of hydrocarbons with an even number of carbon atoms (Table 1). This occurs because C_3 hydrocarbons are formed by reaction of C^+ with C_2H_2 while C_4 hydrocarbons are produced by the reaction of $C_2H_2^+$ with C_2H_2 . Since C^+ is more abundant than $C_2H_2^+$, C_3H_m will be more abundant than C_4H_m . Subsequent acetylene additions preserve this relation: that is $C_{2n+1}H_m/n > C_{2n+2}H_m/n$.

The fractional ionisation which we have assumed, $e/n \approx 3 \times 10^{-8}$, is an upper limit deduced from observed abundance ratios of isotopic forms of various molecules. It is unlikely that e/n can be much less than 10^{-8} because the observed abundance of HCO^+ is often $HCO^+/n \approx 10^{-8}$, providing a lower limit to e/n if the regions are electrically neutral. Furthermore, model calculations show that, even with extreme heavy element depletion, the fractional electron abundance remains near 10^{-8} (ref. 10). On the other hand, the fractional ionisation in less

Table 1 Predicted relative abundances of hydrocarbons in dense clouds

$C_3H_m/n \approx 1 \times 10^{-6}$	$C_4H_m/n \approx 8 \times 10^{-8}$
$C_5H_m/n \approx 2 \times 10^{-7}$	$C_6H_m/n \approx 2 \times 10^{-8}$
$C_7H_m/n \approx 3 \times 10^{-8}$	$C_8H_m/n \approx 3 \times 10^{-9}$
$C_9H_m/n \approx 7 \times 10^{-9}$	$C_{10}H_m/n \approx 7 \times 10^{-10}$
$C_{11}H_m/n \approx 1 \times 10^{-9}$	$C_{12}H_m/n \approx 1 \times 10^{-10}$

dense and/or warmer regions may be as high as 3×10^{-7} . A fractional electron abundance of 3×10^{-7} would not change the methane abundance⁴, the acetylene abundance, or the abundance of C_2H_m . All other hydrocarbons, C_n/H_m with $n > 4$, would decrease in abundance by a factor of 10 because their precursor ions, $C_nH_m^+$, would decrease in abundance by this factor.

The high abundances we find here for dense clouds ($\Sigma_{m>5} C_m/n \approx 10^{-7}$) lend support to the idea that C_n molecules may be the source of the diffuse interstellar lines.

γ and X rays from the zodiacal dust

γ -RAY lines can be produced by MeV protons in interactions with interstellar¹⁻⁴ and solar coronal matter⁵⁻⁷. Here I show that, in favourable conditions, solar flare protons can produce both observable γ -ray lines and characteristic X-ray lines, when interacting with the material of the zodiacal dust cloud. Of particular interest are narrow γ -ray lines without kinematical broadening ($\Delta E < 1$ keV), which are produced by long-lived

Fig. 1 Idealised mass density as a function of grain size of the zodiacal dust. This was adapted from Giese and Grün's⁶ maximum model. The abscissa shows particle radii for two different assumed grain material densities; also indicated is the corresponding grain mass. This graph shows that the bulk of the zodiacal dust matter is contained in grains with radii $10 \mu m \leq r \leq 100 \mu m$.

Table 1 The most intense nuclear γ -ray lines expected from zodiacal dust matter

Element	Photon energy (MeV)	Mean life (10^{-12} s)	4 August 1972 expected line flux at Earth ($10^{-6} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$)
¹⁶ O	6.23	24.0	1.0
²⁴ Mg	1.37	1.75	1.3
²⁸ Si	1.78	0.68	0.5
⁵⁶ Fe	0.847	9.7	1.2

The line flux expected for the 4 August 1972 event from zodiacal dust oxygen is estimated in the text, the other three values were scaled for differing abundance ratios from ref. 4.

nuclear excited states ($\tau \geq 10^{-12}$ s) in solids. A typical zodiacal dust grain is sufficiently large for such narrow line production, and modern germanium detectors can detect and identify these lines. Observation of X rays and γ rays together would yield information on the average interplanetary dust density, grain size, material density, and chemical composition. This might help to determine whether the dust is of Solar System (for example, cometary) or of interstellar origin. Protons ≥ 10 MeV form a probe for which the dust grains are transparent, so that the measured quantity does not depend on grain size and surface properties, in contrast to the zodiacal light.

The properties of the zodiacal dust are not too well known. The grain size spectrum shows a knee^{8,9} around particle size 3×10^{-7} g, which translates into grain radii (spherical shape assumed) of $r \approx 30 \mu m$ to $r \approx 60 \mu m$, for assumed material densities of $\rho_{\text{mat}} = 3 \text{ g cm}^{-3}$ to $\rho_{\text{mat}} = 0.3 \text{ g cm}^{-3}$, respectively. The bulk of the matter is contained in grain sizes between about 10 and $100 \mu m$ (see Fig. 1). The range of 10 MeV protons is $\geq 0.1 \text{ g cm}^{-2}$, so the grains are transparent up to $r \approx 1,000 \mu m$. The total mass density at 1 AU is somewhere between $4 \times 10^{-23} \text{ g cm}^{-3}$ (refs 8, 9) and $4 \times 10^{-22} \text{ g cm}^{-3}$ (refs 10, 11); in the following, ρ is taken as $1.2 \times 10^{-22} \text{ g cm}^{-3}$. The number density dependence on solar distance R is estimated to be $n(R) \propto R^{-\nu}$ with ν between 1.0 and 1.7 (ref. 12). Recent space probe observations imply that ν from 1.3 (ref. 13) to 1.5 (ref. 14). Around the Sun there seems to be a dust-free zone extending to a few solar radii¹⁵. Infrared observations¹⁶ and orbital calculations¹⁷ indicate that the dust cloud indeed extends down to a few solar radii. The chemical composition of the grains seems to be similar to chondrites^{10,18} or even to carbonaceous chondrites^{19,20}. The material density of the dust particles is often assumed to be between that of water and iron²¹, typically $\rho_{\text{mat}} \approx 3 \text{ g cm}^{-3}$. On the other hand, fluffy particles, which consist of a mosaic of smaller particles and which are probably much less dense, have been recorded^{10,20,22,23}. Other estimates are as low as $\rho_{\text{mat}} = 0.18$ (ref. 11).

Nuclei that are excited by 10–20 MeV protons (where the excitation cross-sections exhibit a broad maximum) receive recoil energies in the 10–100 keV/AMU range⁶. Lines from short-lived states or gaseous material would be of the order of 100 keV wide^{2-4,6}. However, in solids such nuclei have projected ranges of several $100 \mu g \times \text{cm}^{-2}$ (refs 24–26), and their stopping time is of the order of 10^{-12} s, so that lines from longer-lived nuclear states from grains with $r \gg 1 \mu m$ would have a significant component that is very narrow due to lack of kinematical broadening^{3,4,6}. Table 1 lists the most important long-lived γ -ray lines that can be expected from extraterrestrial matter²⁴. These are probably the only lines that will be observable. The carbon 4.44 MeV line is not included because it is short-lived and shows full Doppler broadening in solids, as can be demonstrated in the laboratory²⁷, while the states listed produce a significant narrow component. If the dust were mostly cometary debris, the carbon abundance would be too low to produce an observable line flux anyway.

The expected line flux of the oxygen 6.13 MeV line can be estimated using a grain composition similar to carbonaceous chondrites (see ref. 28), that is $\approx 40\%$ O, $\approx 20\%$ Fe, $\approx 10\%$ Si, $\approx 10\%$ Mg by weight, which for $\rho = 1.2 \times 10^{-22} \text{ g cm}^{-3}$ yields 1.8

O-atoms, 0.26 Fe-atoms, 0.26 Si-atoms, and 0.3 Mg-atoms per cm^3 . This is about 300–1,000 times larger than in the interplanetary gas (see ref. 30).

The emissivity per unit volume is $P_\gamma = \int_0^\infty n \cdot \sigma(E_i, E) \cdot F_p(E) dE \text{ cm}^{-3} \text{ s}^{-1} \text{ sr}^{-1}$, where $n \text{ cm}^{-3}$ is the number density of the nucleus under consideration, $\sigma(E_i, E)$ is the total cross-section for production of a photon of line energy E_i by a proton of energy E , and $F_p(E) \text{ cm}^{-2} \text{ s}^{-1} \text{ MeV}^{-1}$ is the flux of energetic protons. Oxygen cross-sections by Ramaty *et al.*³⁰ are used in an example of the 4 August 1972 particle event with a proton spectrum $F_p(E) = 1.7 \times 10^6 (E/\text{MeV})^{-1.7}$. To determine this spectrum the spectral shape and α/p ratio ($\approx 3\%$) before and after the maximum phase of the event were adapted from ref. 31. Then the maximum phase α -particle flux from ref. 32 was multiplied by 30, because the proton flux measurement suffered from detector saturation. Although the proton flux thus derived is larger than reported elsewhere, it is a realistic estimate because most of the proton detectors in space were probably saturated during the flux maximum. With these values $P_\gamma \approx 7 \times 10^{-20} \text{ cm}^{-3} \text{ s}^{-1} \text{ sr}^{-1}$. Assuming the lateral extent near Earth of this event to be about 1 AU, the total flux at Earth becomes $F_{6.13} \approx 10^{-6} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (see also Table 1). This is about 10–20 times smaller than the sensitivity threshold of currently planned γ -ray detectors in space (aperture of $\approx 1 \text{ sr}$ assumed).

Larger γ -ray fluxes may be observed, for the following reasons: (1) the largest estimates of the dust density are three times the value used here^{10,11}, (2) Conservative extrapolation of particle event statistics³³ indicate the possibility during maximum solar activity of several events per year of the August 1972 size, and ≥ 1 event yr^{-1} of ≥ 10 times that size, occurring all over the visible hemisphere of the Sun. On Earth only those events originating near the preferred solar longitude³³ will be seen as strong particle events, while all events can be seen in γ rays. (3) The detector could view the Sun directly as after the short flash phase of the flare the Sun will be quiet again³⁴, causing no background. Assuming that the proton density (or flux) rises as R^{-2} towards the Sun, and the dust density as $R^{-1.3}$ to $R^{-1.5}$, the γ ray line flux at Earth from the solar direction can be 15–30 times larger than estimated above. Thus, despite the first low estimate above, there is a good chance that these γ -ray lines can be observed in the future.

Protons of this energy also ionise with fairly large probability the K -shells of atoms, while at the same time they generate little continuum X-ray background. The product of proton flux and cross-section peaks at less than 1,000 U_K (where U_K is the K -absorption edge energy), which is as low as 0.5 MeV for oxygen. Grains are not transparent to these protons or to the corresponding K_α -photons. Yet, the characteristic K_α lines should be observable.

K_α line fluxes will be estimated in a way similar to that used for γ -ray line fluxes, the main difference being that the grains are not transparent except for the 6.42 keV K_α line of iron. For simplicity I assume that half the photons that are produced in the outer layer of the grain of thickness $1/(\mu/\rho) \text{ g cm}^{-2}$ leave the grain and can be observed (μ/ρ is the mass absorption coefficient). This 'active' fraction of the total mass of the dust depends on grain material density and composition, and therefore estimates are given for $\rho_{\text{mat}} = 3 \text{ g cm}^{-3}$ and $\rho_{\text{mat}} = 0.3 \text{ g cm}^{-3}$.

Table 2 The most intense K_α lines expected from the zodiacal dust during a solar proton event

Element	K -shell ionisation energy (U_K) keV	K_α -mass absorption coefficient (μ/ρ) $\text{cm}^2 \text{ g}^{-1}$	K_α -line energy keV	4 August 1972 expected K_α -line flux at Earth for grain density $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$	
				$\rho_{\text{mat}} = 3$ g cm^{-3}	$\rho_{\text{mat}} = 0.3$ g cm^{-3}
O	0.53	6.5×10^3	0.52	1.9×10^{-3}	6.6×10^{-3}
Mg	1.31	2.5×10^3	1.26	5.0×10^{-4}	1.5×10^{-3}
Si	1.85	1.3×10^3	1.74	6.8×10^{-4}	1.8×10^{-3}
Fe	7.14	1.0×10^2	6.42	1.5×10^{-3}	1.7×10^{-3}

Fluffy particles probably behave like low density material.

To compute the mass absorption coefficient I have added 20% Ca to the chemical composition assumed above. This should account approximately for the rest of the material which is a mixture of elements ranging from carbon to at least nickel²⁰. I have used experimental and computed mass absorption coefficients^{35,36} and K -shell ionisation cross-sections³⁷, and published quantum yield values³⁸ to derive Table 2. The last two columns of Table 2 contain flux values expected for the 4 August 1972 event.

The main problem for registering these fluxes is caused by the diffuse X-ray background of the sky, which at 6.4 keV is about 0.6 photons $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ keV}^{-1}$ (refs 39, 40). Taking this into account, the expected Fe- K_α flux is about a factor of 3 below the sensitivity threshold of large orbiting X-ray detectors (on HEAO 1). In this case, only a three times larger dust density, or a three times larger particle event would be required for positive detection.

The moon should emit γ -ray lines and X-ray lines by the same mechanisms. In case of the 4 August 1972 event, the oxygen 6.13 MeV line flux at Earth should have been $>10^{-3}$ photons $\text{cm}^{-2} \text{ s}^{-1}$ (40% O by weight assumed), and the 6.42 keV Fe characteristic X-ray line flux should have been >0.5 photons $\text{cm}^{-2} \text{ s}^{-1}$ (10% Fe assumed). Proton-stimulated characteristic X-ray emission as compared to X-ray fluorescence from the lunar surface could be of interest to a possible lunar orbiter mission. The solar X-ray spectra are very soft so that not much intensity is expected in energetic fluorescence lines like the 6.4 keV Fe line, while the MeV protons could stimulate these lines in measurable quantities.

Finally, after large solar flare particle events, it is worthwhile to look at γ - and X-ray lines caused by interactions of MeV protons with the zodiacal dust. For MeV protons and γ rays the dust grains are transparent, so that some data can be derived without complicating grain size and surface effects: the mean composition can be derived in a model independent way, and together with *in situ* measurements of the proton flux it can be used to calculate the average spatial density along the line of sight. X-ray observations with some existing knowledge of the grain size distribution and its dependence on solar distance, can be used to give data on the size and material grain density. On the other hand, if the dust properties were sufficiently well known, large particle events could be monitored at other than the preferred heliolongitude.

I thank R. Ramaty for critical discussions. Part of this work was carried out while I was a NAS-NRC Research Associate at the Laboratory for High Energy Astrophysics at NASA-Goddard Space Flight Center in Greenbelt, Maryland.

The influence of dynamic loading on sliding friction

THERE have been many studies of the rheology of thin polymeric films in sliding contacts¹⁻⁴, and many of the results have been obtained with a particular experimental arrangement which involves studying the motion of a glass hemisphere traversing a thin film deposited on a smooth glass flat³⁻⁵ (Fig. 1). The development of this subject has concentrated on an important quantity of practical interest, τ , the interfacial shear strength, which may be considered to be the energy dissipated per unit distance per unit contact area. These dissipative processes occurring in a particular film are not generally known. The interfacial shear strength has been found, for a wide range of organic polymers, to depend on many parameters, such as

Fig. 1 Schematic diagram of the experimental arrangement. A glass sphere of radius r is loaded against a glass plate on which is deposited a thin organic film of thickness h (typically 100 nm). The surfaces are set in relative motion with a velocity v by the application of frictional force, F , orthogonal to the normal load, W . To a good approximation the area of contact and also the area of film sheared, A , is given by $\pi(W/Kr)^{2/3}$ where K is $\frac{2}{3}(1-\nu^2)/E$ where E and ν are respectively the Young's modulus and Poisson's ratio of the glass⁶. The contact diameter, d , is $2(A/\pi)^{1/2}$ and the intrinsic contact time, t_0 , is d/v . The interfacial shear strength, τ , and mean contact pressure, P_m , are respectively F/A and W/A . The effective rate of strain, $\dot{\epsilon}$, in the film is v/h . Because the mechanical properties of the glasses are invariant with respect to temperature and time, changes in τ in these variables can be attributed wholly to the response of the organic layer. Typically P_m is of the order of 10^8 - 10^9 Pa; $t_0 \sim 0.1$ s and $\dot{\epsilon}$ exceeds 10^3 s⁻¹. Classical calculations suggest that adiabatic heating is trivial in these experiments⁷.

contact pressure, temperature and strain rate, for which simple empirical relations have been found⁵. Providing the real area of contact can be estimated, these relationships are of value in predicting the friction of certain lubricated contacts. These relationships are broadly similar to those obtained from the study of the variation of the bulk yield stress of polymers and in certain cases the magnitude of the fitting coefficients (for example, τ_0 and α below) are similar for a given polymer, in bulk and interfacial shear tests. Direct comparison is difficult because interfacial shear measurements generally correspond to much higher pressures and effective strains and rates of strain. However, it seems that τ may be considered a measure of the bulk shear yield or rupture stress of the organic layer in relatively intense deformation conditions. Using a modification of the basic experimental method we have now obtained detailed information on the effect of velocity or contact time on τ .

For the present note it is only necessary to recall that τ is generally an increasing linear function of contact pressure and

$$\tau = \tau_0 + \alpha P_m \quad (1)$$

where τ_0 and α are constants and P_m is the mean effective contact stress (Fig. 1). For organic polymers α is large (0.1-0.6) and for metals and inorganic solids, it is a factor of between 10 and 100 smaller. More recently, further dependent variables have appeared, for example, film preparation conditions⁸ and with reference to this note, contact time, t_0 (ref. 9). In this context, the intrinsic contact time is approximately the contact length divided by the sliding velocity (Fig. 1).

Previous studies of the velocity dependence of shear strength for a variety of polymers⁵ showed that generally this quantity increases with velocity or effective rate of strain. The variation of τ seems to be a linear function of $\ln \dot{\epsilon}$ consistent with the response of bulk polymers at lower rates of strain. Although the evidence is not conclusive, it seems that τ_0 , but not α , is an increasing function of $\dot{\epsilon}$. One exception was found, polymethylmethacrylate (PMMA), which when studied at room temperature, showed a decrease. PMMA at 160°C ($T_g = 110^\circ\text{C}$) shows an increase of τ with increasing velocity.

Apart from the generation of an effective strain rate, the nature of such a sliding experiment involves the transient application of a normal stress on the film due to the load in the contact. Thus an infinitely thin element of film (Fig. 1) is subjected to a progressive increase in P up to $3/2 P_m$ followed by a decrease to zero as it leaves the contact. The form of this pressure cycle is given by the hertzian pressure distribution in the contact. It has been hypothesized that the effective (or fictive) contact stress in a viscoelastic material will be somewhat less than that which is applied, due to the inability of the film to respond to the rapid variation during sliding¹. In this way the shear strength may be considered to be attenuated through the pressure term in equation (1), where P_m becomes a fictive pressure and a function of t_0 .

Direct experimental confirmation of this hypothesis is difficult, because in practice only small changes in t_0 through d can be effected and the variation of v increases $\dot{\epsilon}$. We have introduced a modification to the basic experimental technique which uniquely elucidates the effect of contact time. A periodic loading was superimposed on the hemisphere by means of a steel core coil fed by an a.c. signal resulting in a signal of amplitude about one-tenth of the 'dead' load. In this way a second (extrinsic) contact time is introduced. To compare polymers a loading frequency of 1.5-30 Hz was used. The frictional force responds with a superimposed ripple which may be extracted from dead load friction using a phase-sensitive detector. The ripple amplitude may then be measured as a function of frequency. As a measure of the attenuation of the sinusoidal signal as a function of frequency, a relative attenuation factor, R , was defined as

$$R = \frac{\Delta \text{Ripple amplitude}}{(\text{Ripple amplitude})_1} \frac{f_1}{f}$$

Table 1 gives values of R for a variety of polymers as well as graphite, MoS₂ and stearic acid for an intrinsic frequency of

Table 1

R	Material
0.45	Molybdenum disulphide
0.45	Stearic acid
0.46	Graphite
0.52	Polyvinyl acetate
0.49	Polycarbonate
0.48	High density polyethylene
0.50	Polystyrene
0.75	Polymethylmethacrylate (room temperature)
0.50	Polymethylmethacrylate (temperature 160 °C)

5 Hz. PMMA at room temperature is the only polymer with high R , confirming that the response of the film is highly contact time sensitive. All other polymers including PMMA at 160 °C show $R = 0.48-0.52$. It thus seems that the dynamic loading technique discerns the influence of contact time and the results are consistent with the velocity behaviour previously obtained. Note that the values of R for non-polymeric solids are slightly lower, indicating that all the polymers studied show some attenuation with contact frequency increase. It would be expected that the non-polymers would not show any retardation in response, and thus $R = 0.45$ seems to be the 'zero' of the technique. Ideally, R should be zero for these films but the apparatus probably has viscous or elastic damping associated with it, although no direct mechanical damping was used.

We have also studied the influence of dynamic contact frequency for a range of intrinsic contact frequencies (generated by maintaining P_m constant and changing v and d). Both the form and magnitude of the attenuation were found to be a function of intrinsic contact frequency. Thus the two loading processes seem to interact for all polymers but the nature of this type of interaction is conceptually difficult to rationalise.

This attenuation of response with contact time decrease has been termed viscoelastic retardation in compression. Previous studies^{10,11} have put forward evidence for its occurrence in oil film shear, although this interpretation was subsequently questioned¹². Recently Johnson and Tevaarwerk¹³ found some evidence that was consistent with a delay in response of oil films. They also showed a general similarity in behaviour between thin oil films in elastohydrodynamic contacts and thin polymeric film shear. There is also some evidence that the low strain properties of bulk polymers show some retardation in response following the application of a hydrostatic stress^{14,15}. These data are complicated because of adiabatic heating. In this context it is worth noting that PMMA has a major bulk relaxation (β transition) at ~ 1 Hz at 20 °C (ref. 16), and it may be this dissipative process which is responsible for the retardation in sliding.

This result has implications for the study of stick-slip or intermittent sliding motion. This type of motion may occur when there are viscoelastic interactions between the machine and the sliding process^{17,18}. Simple analysis shows that it is present when a machine is subcritically damped and when either the static frictional force is greater than the dynamic or when the frictional force decreases with increasing sliding velocity. Because the frictional force is made up, in part, from a product of τ and the real area of contact, the retardation process may be an important factor in controlling its occurrence. In addition the experimental method seems to be useful for the study of the time-dependent properties of organic polymers.

We thank Dr J. K. A. Amuzu for his contribution to the preliminary stages of this work and Professor D. Tabor FRS, for his interest. A.C.S. thanks the SRC and British Petroleum, Sunbury-on-Thames, for the provision of a CASE award.

IR studies of long-range surface effects—excess proton mobility in water in quartz pores

LONG-RANGE ordered elements of water structure of micro-metre dimensions have long been suspected to exist near certain aqueous/solid interfaces. However, the evidence has been inconclusive¹ and it has also been argued that such ordered elements of water structure exist near a glass surface from a comparison of the diffusion coefficients of the hydrogen ion from polarography and the sintered glass diaphragm cell method^{2-4,10}. The pore size of the sintered glass varied between 4 and 15 μm . The mobility of the hydrogen ion is known to be very sensitive to the structure of water^{5,6}. We present here convincing evidence from an IR spectroscopic study of 1M HCl in porous silica that such long-range ordering effects exist near a quartz surface and that as a consequence the excess proton mobility is reduced. Such long-range effects have not been conclusively demonstrated previously. With acid solutions the interaction between the easily polarisable hydrogen bonds of H_2O_2^+ groupings may favour such a long-range order and as the absorbance of the polarisable hydrogen bonds is sensitively influenced by all interaction effects this order may be indicated by changes of the IR continua.

The method of detecting long-range surface effects consists of measuring the absorbance of the continuous absorption observed in acid and base solutions beginning at 3,200 cm^{-1} and extending to smaller wave numbers. It has been shown⁷ that the

Fig. 1 Spectra of water (a) and 1M HCl (b), effective thickness $31.8 \pm 0.5 \mu\text{m}$, absorbed in porous quartz (pore size 4-15 μm).

Fig. 2 Calculated difference spectra, that is the spectra of continuum for 1M HCl, effective thickness $31.8 \pm 0.5 \mu\text{m}$, absorbed in quartz pores (●); and for film of 1M HCl, thickness $32.0 \pm 0.2 \mu\text{m}$ between parallel silicon plates (○).

continuum is due to the H_3O_2^+ groupings in the case of acids and the H_3O_2^- grouping in the case of bases. The phenomenon is not confined to acids and bases and has been observed whenever there is a grouping with a hydrogen bond in which a potential well with a double minimum or a flat broad potential well is present. Such cases have been observed in aqueous and non-aqueous solutions⁷. Furthermore, it has been demonstrated that such H-bonds are extremely easily polarisable. The polarisability of such H-bonds is about two orders of magnitude greater than the usual polarisabilities and hence they interact strongly with the environment, for example, by induced dipole interactions with ions and with dipole fields of the solvate and solvent molecules and particularly with each other. The energy surfaces of the easily polarisable hydrogen bond in H_3O_2^+ becomes strongly deformed by these interactions. As the strength of these interactions shows a broad distribution, a continuity of energy level differences occurs which is observed as continuum in the IR spectra. On the other hand, crystals containing H_3O_2^+ , for example, give broad bands⁸ in the IR spectrum instead of a continuous absorption because the H_3O_2^+ ions are held in rigid crystalline lattice and do not experience the fluctuating random electric fields of a solution. The presence of the continuum with aqueous acids indicates that protons are fluctuating between two boundary structures I and II

If the continuum decreases due to some external field this means that the hydrogen bond becomes polarised, the proton lingering time is greater at one of the two water molecules in the H_3O_2^+ grouping and the proton fluctuation frequency has decreased⁷. Consequently any influence which modifies the normal fluctuating structure of water containing, for example, H_3O_2^+ grouping should also influence the continuous IR absorption. If the influence structures the water causing an asymmetrical environment of the H_3O_2^+ groupings then the continuum should decrease and if, on the other hand, the influence renders the normal bulk structure of water containing the H_3O_2^+ groupings more random, then the continuum should increase⁹. Such effects have been observed on adding electrolytes to aqueous solutions of strong acids⁶.

Disks of sintered quartz 30 mm diameter and 4 mm thick (Heraeus) were each sliced into two disks of the same diameter as the original disk and the resulting disks were ground with a diamond wheel to a thickness between 130 and 100 μm . Only water without any additives was used in the cutting and grinding processes and the disks were held in a special holder without any

adhesive. After grinding, the disks were placed in water and treated with an ultrasonic vibrator to remove any loose particles. The ground disks were chosen for the IR study on the basis of the uniform appearance under the microscope. Water and 1M HCl were absorbed in the disks and the difference in weight between the wet disk, which was carefully blotted between filter papers, and the dry disk was determined. Using also the diameter of the disk, 30 mm, the effective thickness of the liquid could be calculated. For the IR measurements the porous quartz disk was held between thin clear optically flat quartz plates in a special holder to avoid evaporation.

The transmittance of the disks was $<4\%$ in the region 3,000–2,400 cm^{-1} and hence it was not possible to obtain reliable spectra with an optical-null IR spectrophotometer. All spectra were obtained with an electrical-null, ratio-recording Perkin-Elmer 580 at an ordinate expansion of 20 $\times$. On the expanded scale the transmittance was reliable to 0.4%. The disk was placed in the sample beam and the transmittance recorded.

Figure 1 shows the spectra for water and 1M HCl absorbed in a porous quartz disk at an effective thickness of $31.8 \pm 0.5 \mu\text{m}$. Reproducibility was excellent. Figure 2 shows the calculated difference spectra (the spectra for the continuum) between 1M HCl and water absorbed in porous quartz ($31.8 \pm 0.5 \mu\text{m}$ thickness), and 1M HCl and water as thin films between silicon plates ($32.0 \pm 0.2 \mu\text{m}$ thickness). The two spectra are identical in shape but that for porous quartz shows a higher transmittance, that is the absorbance of the continuum for 1M HCl is less when

Fig. 3 Dependence of absorbance of continuum on effective thickness of 1M HCl at $2,560 \text{ cm}^{-1}$ absorbed in porous quartz (pore size 4–15 μm) (○) and as film between silicon plates (●).

absorbed in porous quartz of 4–15 μm pore size range. The identical shapes of the spectra seem to eliminate optical effects as a cause of lower absorbance in porous quartz, as such effects are strongly wavelength dependent and would affect the shape of the spectrum differently at different wavelengths.

The absorbance of the thin films of 1M HCl and water between parallel silicon plates was determined with a special holder described previously⁶. Figure 3 shows the absorbance of the continuum of 1M HCl at $2,560 \text{ cm}^{-1}$ plotted against the effective layer thickness for 1M HCl as a film and absorbed in porous quartz. At all thicknesses studied, the absorbance of the continuum for 1M HCl absorbed in quartz was less than that for the film.

The large depression of the continuous absorption must be caused by a polarisation of the H_3O_2^+ groupings by their local environments. The fluctuation frequency of the excess proton between structures I and II is decreased. The only source of asymmetry of the local environments at the H_3O_2^+ groupings can be a long-range order of the liquid structure by the surface of the pores. Thus, the decrease in intensity of the continuum of H_3O_2^+ in quartz pores indicates the order which may be favoured by interactions of the easily polarisable hydrogen bonds with the environment and especially with each other.

In principle this method of observing long-range surface forces could be extended to non-aqueous systems containing a solute with a high polarisable H-bond. Zundel has discussed such systems elsewhere⁷.

N.K.R. thanks the Deutscher Akademischer Austauschdienst for a grant as a visiting academic at the University of Munich. We thank Wilbur Smeed for preparing the thin porous quartz disks, P. Boar for the use of a Perkin-Elmer 580, electrical-null, ratio-recording IR spectrophotometer, and Dr David Pullin for helpful comments.

Radiation-induced shrinkage of voids in molybdenum and TZM

SINCE the discovery of voids in neutron-irradiated stainless steels by Cawthorne and Fulton¹ considerable effort has been made to obtain experimental data on the nucleation and growth of voids and to understand the processes involved. The phenomenon has been of interest to the designers of fast reactors and could also be an important factor in material development for fusion reactor requirements. From both experiment and theory it is generally expected that for irradiations in constant temperature conditions, the voids will grow and the total void swelling increase with increasing displacement damage. Results are presented here which are contrary to this behaviour and show that in molybdenum and its alloy TZM (Mo, 0.5% Ti, 0.1% Zr), conditions exist where voids initially grow but then shrink as the irradiation proceeds.

High purity zone refined molybdenum² and TZM, both in recrystallised condition, were irradiated in the Dounreay fast reactor to total neutron doses of 1.5, 3.5 and $8 \times 10^{26} \text{ m}^{-2}$ giving calculated damage levels of 7.5, 17.5 and 40 displacements per atom respectively. The highest dose specimens were obtained by re-irradiating some of the specimens after the 3.5×10^{26} radiation. All the specimens discussed here were irradiated in

instrumented rigs at temperatures of $450 \pm 25^\circ \text{C}$. They were in the form of 3 mm disks and were examined after irradiation and after suitable electro-polishing by transmission electron microscopy in a Philips EM400 microscope. This system enabled voids with diameters $>0.8 \text{ nm}$ to be resolved.

The main results from the microscopy study are given in Table 1. The general result of a high density of voids and the appearance of loops agreed with previous high-dose neutron radiation studies of molybdenum and TZM near 450°C (refs 4–8). Similarly, the observation of void and loop lattices was not unusual. The unexpected result was the absence of visible voids in the high-dose TZM specimens. As it was known that these specimens contained voids before their second irradiation, it was at first thought that some aberration, such as a high temperature excursion (the most obvious way to remove voids) must have occurred. This was ruled out by two factors, namely the rig temperature records and the presence of voids in commercial molybdenum packing disks irradiated adjacent to the TZM specimens. However, when all the results are examined it becomes clear that the TZM result is the end product of a general irradiation process involving, first, the formation and growth of voids and, finally, their radiation-induced shrinkage. In the highest dose molybdenum specimen the large reduction in void swelling is clear but Table 1 also shows, when the void concentrations are examined, that the void shrinkage processes were already in operation during the medium dose irradiation. This is supported by evidence from void density histograms⁹ where the differences between the low and medium doses clearly show the simultaneous shrinkage of small voids and the continued growth of larger voids.

Some aspects of the dislocation loop structure are also of interest. The high loop density is evident in all the TZM specimens and also in the high-dose molybdenum shown in Table 1. The diameter of these loops, close to 5 nm, was surprisingly uniform. An important point was that the loops were indirectly established to be vacancy in nature; loop analysis procedures were carried out in annealed specimens where the fine loop structure had coarsened sufficiently to allow unambiguous identification. The loop lattice was apparent only in the presence of a void lattice. Since the results on molybdenum show the existence of a void lattice before loop growth, it implies that vacancy loop growth takes place preferentially on vacant void lattice sites.

The normal situation where voids acquire vacancies during the displacement damage process has been adequately explained elsewhere. The dislocations in the system have a preference, or bias, for interstitials leaving a supersaturation of vacancies to be captured by less biased, or neutral, sinks such as voids. To explain the observed void results, some mechanism must be invoked that allows a net flux of interstitials to the voids. It seems impossible to envisage any process taking place at a dislocation network to give this effect; instead such a situation is most likely to be achieved by some cumulative process inhibiting the jump of vacancies into a void. The presence of vacancy loops in the system supports this proposal. In particular it is significant

Table 1 The variation of void and loop parameters in Mo and TZM during neutron irradiation at 450°C

Material	Neutron dose (nm^{-2})	Average void size (nm) { $\pm 5\%$ }	Void density (m^{-3}) { $\pm 10\%$ }	Void swelling (%)	Loop density (m^{-3}) { $\pm 25\%$ }	Void/loop lattice parameter* (nm) { $\pm 5\%$ }
Mo	1.5×10^{26}	2.4	2.8×10^{23}	0.22	$\sim 6 \times 10^{20}$	22.2
Mo	3.5×10^{26}	4.4	1.3×10^{23}	0.57	$\sim 6 \times 10^{20}$	23.1
Mo	8.0×10^{26}	4.7	3.5×10^{22}	0.20	6×10^{22}	24.0
TZM	1.5×10^{26}	2.9	1.7×10^{23}	0.24	8×10^{22}	22.0
TZM	3.5×10^{26}	4.7	6×10^{22}	0.34	6×10^{22}	21.8
TZM	8.0×10^{26}	VNF	VNF	<0.01	1.3×10^{23}	—

VNF, voids not found.

* These values close to those suggested for 450°C by Moteff and Sikka³ who have studied the variation of void lattice parameter with irradiation temperature.

that the sharp rise in vacancy loop density in molybdenum takes place after void shrinkage processes have begun. If the voids acquire an effective preference for interstitials to add to the normal interstitial bias of the dislocation network, then it is not surprising that the vacancy concentration in the lattice could rise and allow the net absorption of vacancies in loops. However, the exact behaviour of the loops must clearly depend on their interstitial bias. It is interesting that the survival of the vacancy loops at a time when large voids are still growing (a situation certainly found in the medium-dose TZM specimens) supports the recent proposal¹⁰ that small vacancy loops must have a weaker interstitial bias than the network dislocations. The rather uniform loop size could also be significant in this context, as the vacancy loops might only grow to a size at which their neutrality with respect to the network is lost.

These results demonstrate that in both molybdenum and TZM, neutron irradiation can induce void growth and later, without any change in irradiation parameters, induce void shrinkage. A self-consistent explanation of the void and associated loop behaviour is that some mechanism first causes the smaller voids and later the larger to lower their probability of vacancy capture and hence allow a net influx of interstitials to their surfaces.

The void shrinkage in two materials of widely differing purity and the relatively slow increase in the effect during irradiation point to the mechanism being associated with the migration of transmutation products to the void surfaces. The segregation of alloying elements¹¹ and transmutation products¹² to voids by the flow of defects is already well known, but Marwick¹³ has recently derived expressions showing that solute atom segregation at voids can result in a void becoming biased against vacancies. Finally, if the effects reported here on molybdenum and TZM are found, or can be induced (perhaps by suitable alloy tailoring) in other materials, the technological interest could be considerable.

I thank Drs A. D. Marwick, R. Bullough and M. Wood for useful discussions.

Fixation of radioactive waste in high silica glasses

THE safe disposal of large quantities of high-level radioactive wastes from spent power reactor fuels, or reprocessing is a problem of considerable concern because of the danger which may arise from their release into the environment. We describe here a multi-barrier vitrification process which is conducted at moderate temperatures (below 900 °C) and which yields the fixation of radioactive wastes as oxides in a high-silica matrix. Some special characteristics of this process are discussed, including the excellent chemical durability, high thermal and structural stability of the glass, and the possibility of multibarrier protection.

The waste materials contain a wide variety of isotopes which

Table 1 Room temperature dissolution of candidate glass matrices

	High silica glass bar	Without bar	Borosilicate glass	Others
Matrix dissolution rate ($\text{g cm}^{-2} \text{d}^{-1}$)	5×10^{-10}	5×10^{-10}		
Concentration of radioactive waste	0.5%*	15%		
Rate of dissolution of waste material ($\text{g cm}^{-2} \text{d}^{-1}$)	2.5×10^{-12}	7.5×10^{-11}	3×10^{-4} to 3×10^{-3}	10^{-4} - 10^{-7}

* Concentration in the protective barrier; interior concentrations were at 15%.

emit all forms of radiation and therefore must be isolated from the environment. Most wastes are processed to salt form in aqueous, usually acidic solutions. The radioactivity levels of the waste materials in concentrated form are very high, with a high associated thermal power output¹. Waste forms may be kept at relatively cool temperatures (80 °C) with constant cooling. However, if cooling is not possible within the first century after removal from the reactor, the wastes may attain temperatures of several hundred degrees during this period. Although the actual thermal history of the solidified wastes is still a matter of debate it is becoming apparent that storage below 100 °C is desirable to maintain the structural and chemical integrity of the disposal medium. In addition, the fixation materials will receive high radiation doses and may undergo structural rearrangements. Finally, due to the constantly occurring radioactive decay processes, many isotopes will alter their chemical state and properties; most significantly, some species will give rise to secondary products in different physical states, such as the formation of He by α -emission. These transformations may stress the containers intolerably and lead to break-up or explosions which in turn expose a far larger surface area of the waste material to environmental attack. Therefore, the rate of chemical dissolution of the radioactive wastes in aqueous and saline solutions, and the structural stability, strength and He gas permeability of the various fixation materials determine the safety of the disposal systems for these wastes.

One promising approach to the problem of disposal is the process of fixation in oxide glasses². Glasses can withstand high ambient temperatures better than plastics or concrete, and have better durability than metals, especially in saline solutions. However, properties of glasses vary extensively with composition, and while glasses in general exhibit better chemical and physical durability than most other materials, a wide range of durabilities are possible depending on composition. For example, a glass such as B_2O_3 is immediately dissolved in water, yet other glasses show only small traces of corrosion even after millions of years³. In fact, with some glass compositions, the resistance to chemical attack achieved may be so high as to make possible beneficial uses of nuclear waste materials, such as for Cs and Sr radiation sources, without any danger of contamination of the environment.

The glass fixation schemes proposed in the past involve melting glass at relatively high temperatures⁴. Radioactive waste materials, however, must remain relatively cool to minimise the vaporisation of the volatile radioactive fission products including the alkali metals and the oxides of Ru. The most promising previous scheme using a zinc borosilicate glass was a compromise necessitated by the requirement to stay below 1,100 °C during melting². The compromise involved choosing a glass with very low silica content (<40%) to lower the melting temperature. The chemical durability exhibited by this glass, while better than that of many glasses, is considerably less than is achieved in good chemical labware, for example.

Good chemical durability in glass is generally achieved by

Fig. 1 Diagram of molecular stuffing process for the fixation of radioactive wastes.

increasing its silica content and decreasing alkali ion content as much as possible. This effect was observed with tektites retrieved from the ocean floor which show negligible chemical attack after 750,000 yr when the silica content is above 60% by weight³. These tektites, when measured in the laboratory, exhibit dissolution rates in water of approximately $0.5 \text{ \AA d}^{-1}$ (ref. 6).

Tektites have also provided information concerning the resistance of glass materials to devitrification over extended periods. Samples 35 Myr old have been found which are completely glassy and moon rocks have shown glassy phases over 4,000 Myr old without traces of crystallisation⁷.

The clue to high chemical durability and high structural stability seems to be high content of silica and other glassformers and low content of the alkali metals and other structure modifiers. Preliminary measurements of the compaction of glasses under high-level irradiation have shown that silica glass undergoes relatively little change⁸. Therefore, it is clear that high silica glasses will optimise the properties which characterise a desirable material for the fixation of radioactive wastes. However, preparation has been a problem since high temperatures (1,800 °C) are needed to melt glasses with a high silica content.

Recent research with a process for adding dopants to high silica porous glasses at relatively low temperatures (below 900 °C)⁹ has led us to develop a method suitable for the fixation of radioactive waste materials in a high silica glass.

The process uses a high-silica porous glass which can be prepared by melting an alkali-borosilicate glass, heat-treating it to induce phase separation into a high silica and a low silica phase and dissolving the latter by leaching in an acid solution which does not attack the high-silica phase. A porous glass with an interconnected porous structure and pore sizes from 100 to 500 Å is thus formed and consists of 96% SiO_2 and 4% B_2O_3 . The melting, phase separation and leaching operations are shown in steps 1, 2 and 3 of Fig. 1.) These steps are non-radioactive and may be conducted in a separate plant. Step 1 which requires a temperature of 1,400 °C, however, causes no problem of volatilisation of toxic materials since this is a simple non-radioactive glass melting operation.

The porous glass is then taken to a waste fixation plant and is subsequently soaked in a solution containing the prescribed

radioactive waste materials in salt form (see Fig. 1, step 4). These can be nitrates or other salts which decompose to oxides below 700 °C. After a soaking period of several hours, which allows the pores to fill completely with the solution, the laden porous glass is removed from the solution and the salts present in the pores are precipitated by undercooling. The porous glass is then soaked in a clean solvent which removes the waste material salts from an outer layer of porous glass at the surface of the glass object (see Fig. 1, step 5). The solvents are subsequently evaporated and the porous glass is heated slowly to between 625 and 700 °C to complete the drying and to decompose the waste material salts to an oxide form. Further heating to 900 °C sinters the structure by viscous flow, thus collapsing the pores and yields, on cooling, a solid glass object containing the radioactive waste materials interstitially in the interior (core region) and a high silica envelope on the outer surface (cladding region) (see Fig. 1, step 6). The core region consists of 75% SiO_2 and approximately 20% radioactive waste loading; the cladding region consists of 95% SiO_2 and is relatively free of waste materials (less than 0.5%). The cladding region can be made with any desired depth. An additional benefit of the difference in composition between the core and the cladding regions is the large surface strengthening obtained in these samples arising from a difference in the contraction of the two regions in cooling after fabrication. The clad region being of higher silica content has a lower coefficient of thermal expansion and is therefore fabricated with a large surface compressive stress which enhances the strength and stress corrosion resistance of these samples¹⁰.

We have made many samples with a number of dopants, most notably caesium oxide because it poses a significant problem as a radioactive waste material with its low vaporisation temperature, its high diffusion coefficient in glass and its high level of γ -radiation.

When caesium was used as a single dopant, the caesium oxide distribution in the finished rods was 15% by weight in the core and <0.5% in the clad, with the remainder of the glass being 4% B_2O_3 and the rest silica. (Note that this is a concentration of SiO_2 above 90 mol per cent.) We report, below, data on caesium-doped samples. We have also made samples containing mixtures of Fe, Sr, Y, Zr, Cs, Ba, La, Ce and Nd as nitrates, simulating a

Fig. 2 Time dependence of room temperature dissolution rates for a high-silica glass matrix and for one with a 15% dopant concentration. O, Doped glass (15% loading); A, base glass.

Pw7—a waste stream² with equally successful results.

We have tested the chemical durability of rods containing 15% Ca_2O and rods without dopant by immersing them in distilled water at room temperature and at 100 °C for various times up to 10 d in a Teflon beaker. The chemical durability was related to the amount of silica released by the rods into the distilled water. The dissolution rate at room temperature is shown in Fig. 2 as a function of time for both types of glass. After 10 d in water, at room temperature the dissolution rate of the loaded rod is down to 0.02 Å d^{-1} ($5 \times 10^{-10} \text{ g cm}^{-2} \text{ d}^{-1}$) following a square root behaviour with time. The base glass dissolution rate is down to 0.01 Å d^{-1} after the same time period. At 100 °C the dissolution rate of the doped glass was measured to be $4 \times 10^{-6} \text{ g cm}^{-2} \text{ d}^{-1}$ after 2 d and $2 \times 10^{-6} \text{ g cm}^{-2} \text{ d}^{-1}$ after 4 d.

There are two mechanisms which may control the rate of release of caesium into the bath. The first corresponds to caesium ion diffusion through the glass to the surface, while the second corresponds to the dissolution of the surface itself. The diffusion coefficient for caesium in this glass at 20 °C has been estimated to be $1 \times 10^{-29} \text{ cm}^2 \text{ s}^{-1}$ from electrical conductivity measurements¹¹. This predicts a caesium release rate of $3 \times 10^{-18} \text{ g cm}^{-2} \text{ d}^{-1}$. This value is so small that despite the wide discrepancy usually seen between diffusion coefficients calculated from conductivity measurements and leach rate measurements, it is most likely that the rate of release of caesium from the cladding region of the glass into the bath will be controlled by the rate of surface dissolution and will have a value of $2 \times 10^{-12} \text{ g cm}^{-2} \text{ d}^{-1}$ at room temperature. This number is the product of the measured dissolution rate ($5 \times 10^{-10} \text{ g cm}^{-2} \text{ d}^{-1}$) and the caesium concentration in the clad (0.5%). Since the cladding region is expected to be 1 mm thick, it will take over 1 Myr to dissolve it.

The matrix dissolution rates measured for these samples are extremely low—lower than those measured for long-lived geological glass specimens. Compared to the other glass media being considered for radioactive waste fixation (see Table 1), these high silica glasses exhibit matrix dissolution rates 1,000-fold lower, in comparable conditions, without the additional benefit of the protection which the cladding region offers. As the cladding region developed by this process only contains 0.5% loading, then until the entire clad has been leached, the dissolved glass only contains a 0.5% concentration of waste materials while the glasses without the protective barrier contain concentrations of 15–30%. This provides an additional reduction by a factor of 30–60 in calculating the rate of release of waste materials from glasses made by the molecular stuffing process, giving a cumulative improvement of 10,000 to 1,000,000 times other glass encapsulation processes (see Table 1). Note that even without the barrier, improvements between 300 and 30,000 are still obtained.

These results show that the high-silica glass matrix produced

by the porous glass process could be of value for effective long-term chemical fixation of radioactive wastes. Several questions remain to be studied, such as the effect on durability of pressure, of high levels of radiation and of chemical transmutations.

In conclusion, we have demonstrated that the fixation of radioactive wastes is feasible in high-silica glasses of good chemical durability. An analysis of leaching rates measured on this high-silica glass shows a clear advantage over other fixation media.

Is CS_2 a precursor for atmospheric COS?

THE stratospheric sulphate layer¹ may play a major part in the Earth's global radiation budget^{2,3}. Recent measurements^{4–6} indicated that carbonyl sulphide (COS) has an appreciable concentration, ranging from 0.3 to 0.5 p.p.b. in the Earth's troposphere. The gas is relatively inert^{7,8} in the troposphere and may therefore diffuse to the stratosphere where, through photolysis^{7–9}, it may provide a major source of sulphate for the formation of the stratospheric sulphate layer. Thus, the origin of atmospheric COS is of particular interest in the stratospheric sulphur cycle. Kurylo¹⁰ suggested that the reaction of carbon disulphide (CS_2) with OH might form COS as a reaction product. We investigate this possibility here through global COS budget analysis in the light of new atmospheric and laboratory measurements. Recent measurements showed that CS_2 has a tropospheric concentration of around 0.1 p.p.b.³. The gas has previously been detected in seawater samples by Lovelock¹¹. These measurements seem to suggest that the ocean might be a source for atmospheric CS_2 .

The atmospheric sinks for COS are,

and

Reaction (1) dominates in the stratosphere and may account for a global removal rate of COS of about $2.4 \times 10^4 \text{ ton (S) yr}^{-1}$ based on our 1-dimensional model calculation¹² using measured photolysis cross-sections^{13,14}. Reaction (2) is relatively unimportant. The rate constant k_3 for reaction (3) is uncertain. Removal of COS in the troposphere, however, could be dominated⁸ by reaction (3) if k_3 exceeds $1 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$. Kurylo¹⁰ recently reported a value of $5.7 \times 10^{-14} \text{ cm}^3 \text{ s}^{-1}$ for

k_3 at 296 K, in apparent conflict with an upper limit $k_3 \leq 7 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$ reported by Atkinson *et al.*¹⁵. Assuming a tropospheric OH abundance¹⁶⁻¹⁸ of 10^6 cm^{-3} , one would estimate global removal rates of COS due to reactions (1-3) of $\sim 2.2 \times 10^6 \text{ ton (S) yr}^{-1}$, $2.2 \times 10^5 \text{ ton (S) yr}^{-1}$ and $2.4 \times 10^4 \text{ ton (S) yr}^{-1}$ corresponding to the cases $k_3 = 5.7 \times 10^{-14} \text{ cm}^3 \text{ s}^{-1}$, $k_3 = 5 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$ and $k_3 = 0 \text{ cm}^3 \text{ s}^{-1}$ respectively. The obvious question is whether one can account for the global COS balance in each of the above three cases representing different atmospheric lifetimes of COS.

Atmospheric oxidation of certain sulphur-carbon containing species such as CS_2 and DMS (CH_3SCH_3) might be possible sources for atmospheric COS. For instance, the reaction of CS_2 with OH,

might produce COS¹⁰. The rate constant k_4 is $1.85 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$ according to Kurylo¹⁰ and $\leq 7 \times 10^{-14} \text{ cm}^3 \text{ s}^{-1}$ according to Atkinson *et al.*¹⁵. The products in reaction (4) have not been identified. However, note that reaction (4a) is endothermic¹⁰ by 23 kcal mol⁻¹, while (4b) is exothermic¹⁰ by 35 kcal mol⁻¹. Assuming that reaction (4) proceeds primarily through branch (4b), the flux of COS obtained from integrating the continuity equation is

$$\phi_{\text{COS}}(z=0) = \int_0^\infty \{k_3[\text{OH}][\text{COS}] + J[\text{COS}] - k_{4a}[\text{OH}][\text{CS}_2]\} dz \quad (5)$$

Where J is the photolysis rate of COS and $[i]$ denotes the concentration (molecule cm^{-3}) of the species i . The quantity ϕ_{COS} defined here may be interpreted as a measure of the deficit in the COS budget and may be readily calculated using a standard one-dimensional model¹². If we adopt the observed mixing ratios of COS and CS_2 of 0.4 and 0.1 p.p.b. (parts per 10^9) (refs 4-6) respectively, a first order balance in COS budget may be achieved by adjusting the values k_3 and k_{4a} . For instance, in the above three cases where $k_3 = 5.7 \times 10^{-14} \text{ cm}^3 \text{ s}^{-1}$, $5 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$ and $0 \text{ cm}^3 \text{ s}^{-1}$, the corresponding values for k_{4a} have to be 1.7×10^{-13} , 1.7×10^{-14} and $2 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$ to balance the COS budget. Note that for the first case, the pair of values (k_3 , k_{4a}) is consistent with the values reported by Kurylo¹⁰. While the values for the two latter cases are consistent with the upper limits set by Atkinson *et al.*¹⁵.

Note that when reaction (3) is the dominant loss process for COS ($k_3 \gg 2 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$), a simple relationship between the ratios k_3/k_{4a} and $[\text{CS}_2]_0/[\text{COS}]_0$, where the subscript '0' denotes surface concentration, can be derived from the consideration of COS budget balance. When $\phi_{\text{COS}} \approx 0$ (that is: approximate balance), equation (5) becomes

$$\int_0^\infty k_3[\text{OH}][\text{COS}] dz \approx \int_0^\infty k_{4a}[\text{OH}][\text{CS}_2] dz \quad (6)$$

from which we can derive a ratio $[\text{CS}_2]_0/[\text{COS}]_0$ which is independent of OH concentration by noting

$$k_3[\text{OH}]_0[\text{COS}]_0 H_3 \approx k_{4a}[\text{OH}]_0[\text{CS}_2]_0 H_{4a} \quad (7)$$

where H_3 and H_{4a} are the appropriate scale heights for reactions (3) and (4b) respectively. Since H_3 and H_{4a} are of similar order, the ratio $[\text{CS}_2]_0/[\text{COS}]_0$ is given by

$$R_A = \frac{[\text{CS}_2]_0}{[\text{COS}]_0} \approx \frac{k_3}{k_{4a}} = R_L \quad (8)$$

Equation (8) relates an atmospheric quantity R_A with a laboratory quantity R_L and confirmation of equation (8) will strongly suggest CS_2 as a precursor for COS. Clearly, measurement of k_{4a} requires the detection of COS as a product from reaction (4).

The only atmospheric CS_2 data reported to date are those by Sandalls and Penkett⁵, which seemed to be quite scattered with values ranging from 0.07 to 0.2 p.p.b. However, the lower values should be more appropriate for global conditions. Taking a typical COS concentration⁴⁻⁶ of ~ 0.4 p.p.b. the ratio R_A is ~ 0.18 – 0.5 in harmony with the quantity, $R_L = 0.3$ derived from laboratory measurements of k_3 and k_{4a} by Kurylo¹⁰. In view of the present uncertainties in both atmospheric and laboratory data, the agreement between R_A and R_L may be fortuitous. Nevertheless, relation (8) and similar analysis on other sulphur-carbon containing species (for example, DMS) would provide useful guidelines for identifying the appropriate atmospheric and laboratory measurements which may lead to a better understanding of the origin of COS, and might have interesting implications on the origin of the stratospheric sulphate layer.

We thank C. Howard for useful discussion. This work is partially supported by the Air Force Geophysics Laboratory under contract F19628-78-C0215 and by Manufacturing Chemists Association.

⁸⁷Rb–⁸⁷Sr age of Saint Mesmin chondrite and dating of gas-rich polymict breccia

CHONDRITES are generally regarded as being the oldest objects in the Solar System. However, most of them have suffered severe secondary effects, such as metamorphism, shock and irradiation. The gas-rich polymict breccias have had the most complex history of the chondrites. Some grains of polymict breccias have been exposed to solar irradiation and trapped solar-type rare gases before compaction of the meteorite. Evidence indicates that they were formed in a regolithic environment at the surface of their parent body¹. However, the timing of the successive events which affected the gas-rich chondrites is largely unknown. Saint Mesmin (chemical group LL), is probably the best studied example²⁻⁷ of this class of meteorites. It consists of a dark matrix, rich in solar-type noble gases, which contains light gas-poor xenoliths². The matrix is mineralogically unequilibrated and its material belongs to the chondritic petrological types 4 and 5 (ref. 3). In contrast the xenoliths have been strongly metamorphosed and re-equilibrated and belong to the petrological types 6 and 7 (ref. 3). Also veins of olivine microporphyry run across the meteorite³. Finally, a tectonically incorporated piece of chondrite, of the chemical group H (type H4), has been found in Saint Mesmin⁴. Here, we deal with ⁸⁷Rb–⁸⁷Sr dating of small 10 mg, hand-picked pieces, of the various components of Saint Mesmin. These pieces have been

Fig. 1 $^{87}\text{Sr}/^{86}\text{Sr}$ versus $^{87}\text{Rb}/^{86}\text{Sr}$ plotted for the light xenoliths. Sample names are as given in other studies³⁻⁷. Two digit numbers indicate independent analyses for the same xenolith. Petrographic type is 7 for C3 and L2, 6 for the others³. The inset shows the data for the heavy liquid density fractions from the L6 xenolith. Reference line, 4,480 Myr; $\lambda = 1.42 \times 10^{-11} \text{ yr}^{-1}$; $^{87}\text{Sr}/^{86}\text{Sr} = 0.69877$.

studied by the other techniques³⁻⁷ and have been named by Pellas. Light xenoliths are labelled L1 to L8 and dark samples D1 to D8. One particular light xenolith of petrological type 7 is named C3. Two samples of the type H4 xenolith are named D1 and DD respectively. Where several pieces of the same sample had been analysed independently, we added a second digit to the sample name (for example L81 and L82). We have also analysed heavy liquid fractions of one light xenolith (L6) and of one sample of the H4 type xenolith (DD).

Experimental techniques follow those of Birck and Allègre⁸ and those reported elsewhere⁹. In this study, however, dissolution has only been made in a HF-HNO₃ mixture. New columns and labware meant that some blanks were high (up to 0.1 ng Rb and 0.4 ng Sr) compared with our usual ones (0.05 ng Rb and 0.1 ng Sr).

The results are given in Figs 1 and 2 for light xenoliths and dark samples respectively. (Raw data may be obtained from the authors.) Data for the light xenoliths scatter in the $^{87}\text{Rb}/^{86}\text{Sr}$, $^{87}\text{Sr}/^{86}\text{Sr}$ diagram (Fig. 1). However, most of them plot on a line of age 4,480 Myr ($\lambda^{87}\text{Rb} = 1.42 \times 10^{-11} \text{ yr}^{-1}$), not significantly different from our 'primitive isochron' for chondrites⁹. Our data for heavy liquid density fractions, from the L6 xenolith, are shown on both sides of the reference isochron (inset). If we assume that experimental perturbations by heavy liquids have been negligible, this scatter shows that the ^{87}Rb - ^{87}Sr clock has been partially reset. The repartition of the points can indicate that Rb and Sr redistribution has been closed at the scale of the xenolith. As our samples are rather small, they are probably unrepresentative of each light xenolith. As most of the data plot on the 4,480 Myr reference line this can indicate that all xenoliths are that old, but that the ^{87}Rb - ^{87}Sr system has been perturbed between the minerals of some or all of them. This is also supported by the 4,500 Myr old ^{87}Rb - ^{87}Sr age of Saint Mesmin whole rock¹⁰.

Similarly, samples of the dark components do not define a straight line in Fig. 2. These dark components are, however, of various types: D7 and D8 are samples of the gas-rich matrix; whereas D7 plots on the reference line at 4,480 Myr (samples D71 and D72), D8 plots significantly below (samples D81 and D82). This reveals that the ^{87}Rb - ^{87}Sr system in the matrix has been perturbed at a time younger than 4,480 Myr.

D6 is a gas-poor black xenolith⁷. Our two analyses (D61 and D62) plot on both sides of the reference isochron. As for black hypersthene chondrites¹¹, this result could indicate when this black xenolith was reheated. The slope of the two point-line defined by D61 and D62 yields an age of 1,500 Myr.

Samples of the two microporphyric inclusions D3 and D5 have been analysed⁶. All of them (D3, D51 and D52) plot on the reference isochron. This agrees with their old K-Ar as well as their ^{39}Ar - ^{40}Ar ages^{7,12}. This result is of great importance as these inclusions have been melted and have intruded the meteorite after some brecciation has already occurred⁶. It seems therefore, that the meteorite was brecciated very early in its history. It is interesting that the dark parts of Krähenberg, which are similar to these microporphyric inclusions⁶, also have a 4,600 Myr-old ^{87}Rb - ^{87}Sr age¹³, although this measurement lacks accuracy. Assuming that LL chondrites have had a single parent body, this could indicate that a melting event occurred quite early in its history, and that the melt intruded these two meteorites.

Finally, we have analysed the H4 xenolith (samples D1 and DD), as well as heavy liquid density fractions from sample DD (inset). Whereas the analyses for the whole rock and the heavy fractions of the comparatively large (70 mg weight) sample DD plot on the reference isochron, that for the smaller sample D1 plot well below this line. Figure 3 shows that Rb and Sr are mainly contained in two mineral phases of the xenolith. Whereas the heavier fraction (olivine?) forms an Rb and Sr - poor abundant reservoir, fraction $2.9 < d < 3.1$, consists of Rb- and Sr-rich sparse minerals. The abundances of Rb and Sr in sample D12 (Fig. 3), as well as the position of this sample in the ($^{87}\text{Rb}/^{86}\text{Sr}$ against $^{87}\text{Sr}/^{86}\text{Sr}$) diagram (Fig. 2, inset), indicate that the second phase is enriched in D12 compared with sample DD. Thus, D12 is probably unrepresentative of the average xenolith. Our data on sample DD indicates that this H4 xenolith of Saint Mesmin is about 4,500 Myr old. Its ^{87}Rb - ^{87}Sr system has been perturbed later, possibly due to post-shock reheating. Note that the age defined by DD and the Rb and Sr-rich fraction ' $2.9 < d < 3.1$ ', is 1,200 Myr which roughly agrees with the 1,400 Myr K-Ar age of this xenolith. The strong orientation of the metallic patches in DD indicates that it has been severely shocked. As there is no clear effect in the adjacent parts of the meteorite, DD was probably shocked before its incorporation in Saint Mesmin, and possibly inside the H-chondrite parent-body, 1,400 Myr ago.

Dodd and Jarosevitch⁶ suggest that at least two brecciation events affected the microporphyric inclusions of Saint Mesmin. As discussed above, a first brecciation occurred very early in the history of this meteorite. Our data are ambiguous with regard to younger episodes. First we consider the model ages of our samples relative to the $^{87}\text{Sr}/^{86}\text{Sr}$ initial ratio of chondrites, $^{87}\text{Sr}/^{86}\text{Sr} = 0.69877$ (refs 9, 14). Except for sample C3, they are all older than 4,000 Myr. This could indicate that the irradiation and brecciation history of Saint Mesmin is that old. Such a model

Fig. 2 $^{87}\text{Sr}/^{86}\text{Sr}$ versus $^{87}\text{Rb}/^{86}\text{Sr}$ plotted for the dark xenoliths. For general information see Fig. 1. The inset shows the data for the H-type xenolith.

has been supported by Pellas from U-Th-He and K-Ar data older than 4,000 Myr for most of these samples⁴. However, the two-point isochron of the D6 xenolith may be significant. With the data of the H4 xenolith (sample DD) this can indicate that Saint Mesmin was not yet compacted at that time, and was situated close to the surface of its parent body. This has been argued by Schultz and Signer⁷ on the basis of the K-Ar Age of the H4 xenolith.

Saint Mesmin is composed of 4,480-Myr-old components, many of which have been subsequently thermally disturbed. The foreign H type component can be understood as a residue of an impacting body at the surface of the Saint-Mesmin parent-body. Although their interpretation is not unique, the chronological

Fig. 3 Sr/Rb diagram for the samples and the density separates from the H4 type xenolith. Any fraction can be considered as a mixture of two main minerals respectively contained in fractions $d > 3.3$ and $2.9 < d < 3.1$. D12 is an unrepresentative sample of the mean xenolith.

data support a formation of Saint Mesmin from a regolith at the surface of its parent planet, as recently as 1,400 Myr ago. In particular, the chronological data indicate that the solar irradiation of some grains from the matrix does not correspond to an early irradiation, such as a T-Tauri phase of the Sun.

We thank P. Pellas and G. Poupeau for the samples, and J. L. Birck, G. Manhès, and M. Semet for helpful comments.

A Morarian age for the 'younger Moines' of central and western Scotland

MUCH of our recent knowledge of the Moine metasediments^{1,2}, which extend from the Moine Thrust across the Great Glen Fault to the boundary of the Dalradian Supergroup^{3,4} (Fig. 1), stems from the western Moine region. Here, late-Precambrian, Morarian ages (740-780 Myr) have been established from pegmatites in the Morar Division⁵, and a Grenvillian age ($1,030 \pm 50$ Myr) from the Granitic Gneiss of Ardgour in the Glenfinnan Division⁶. The 'Central Highland Granulites', generally regarded as 'younger Moine'^{2,8}, are little known geologically. Here we briefly outline the results of field (by M.A.J.P.) and radiometric investigations (by O.v.B.) in the Central Highland Granulites and the western Moines, which have fundamental implications for the evolution of these extensive metamorphic rocks, and for the nature of the Grenvillian-Caledonian interval in this sector of the North Atlantic Crust.

Field relationships in the Central Highlands Granulites indicate that the region consists of two fundamentally different assemblages of Moine rocks: a basement, and an overlying cover (Fig. 1). The new name 'Central Highland Division' is used here to describe the basement rocks following Johnstone's use of the term division^{1,7}. The basement and cover are separated everywhere by a zone of tectonic break, called the Grampian Slide. Harris *et al.*⁴ have proposed using the lithostratigraphical term 'Grampian group' for rocks which clearly correspond with the cover assemblage, and their incorporation into the Dalradian

Fig. 1 Sketch map showing the geological setting of the Central Highland Division and the Grampian group: the Central Highland Granulite Region encompasses the outcrop areas of both. P, by Aviemore, centre of the Spey-Dulnain region; GS, approximate trace of the Grampian Slide; ORS, Old Red Sandstone; T, Tertiary and Mesozoic.

Table 1 Rb-Sr isotopic data for muscovite samples in pegmatites

Pegmatite no. and locality	Geological setting	Muscovite sample no.	Rb (p.p.m.)	Sr (total) (p.p.m.)	$^{87}\text{Rb}/^{86}\text{Sr}$	$^{87}\text{Sr}/^{86}\text{Sr}$ (Ri = 0.710)	Apparent age (Myr $\pm$ 0.007)
AB 4 (NH 79500920)	Basement	A	364	13.9	80.64	1.3683	573 $\pm$ 13
		B	367	20.0	62.18	1.2365	594 $\pm$ 13
		C	376	17.0	67.84	1.3303	640 $\pm$ 13
AB 90 (NH 79070937)	Basement	A	320	15.6	62.65	1.3071	668 $\pm$ 13
		B	329	14.1	72.30	1.4201	688 $\pm$ 13
DR 11 (NH 77291305)	Host uncertain	A	450	12.6	113.64	1.7005	611 $\pm$ 11
AF 20 (NH 77821126)	Cover-basement contact	A	317	17.7	54.35	1.1983	630 $\pm$ 14
		B	358	12.9	86.92	1.5695	693 $\pm$ 12
AF 20/8 (NH 77821126)	Cover	A	308	30.6	29.99	1.0116	705 $\pm$ 19
		B	305	29.2	31.13	1.0290	718 $\pm$ 19

All ages calculated with $\lambda^{87}\text{Rb}$ of $1.42 \times 10^{-11} \text{ yr}^{-1}$. Pegmatites AF20, AF20/8 have well preserved D2 fabrics; in AB4, AB90, D3 fabrics modify D2. DR11 is crenulated and retrogressed by a later, post D3 event.

Supergroup. We prefer to describe the cover rocks informally, as the 'Grampian group'.

The Central Highland Division forms most of the ground between Inverness, Forres and Aviemore (Fig. 1). Its dominant rocks are coarse to medium grained, variably gneissose siliceous and quartzofeldspathic metasediments which usually contain variably deformed concordant migmatite. These are interfolded with coarse, commonly migmatitic, quartzites, and with belts of coarse pelitic biotite-gneisses which frequently bear tabular kyanite and sillimanite.

In contrast with the basement, the rocks of the extensive Grampian group are finer grained, less metamorphosed, structurally simpler and essentially non-migmatitic. They form major formations of siliceous flags, semipelitic flags and pelitic schists. The presence of sedimentary structures in most lithologies should make it possible to elucidate regional tectonics and lithostratigraphical successions in this extensive region⁷. Mapping shows that some of the thick pelitic belts of the Central Highland Granulites generally thought to be Dalradian infolds in the Moine^{2,3,8}, such as the 'Grantown Series' and the Ord Ban-river Dulnain belt⁹, belong to a low stratigraphical level in the Grampian group and young upwards without a break into some of the Eilde Flags^{2,7,8}. Reconnaissance indicates that other pelitic belts, such as the Slochd-Streens of Findhorn^{7,9}, belong to the Central Highland Division.

Key evidence for the age relationships of these two rock assemblages stems from structural-metamorphic, stratigraphical and radiometric studies in the Spey-Dulnain watershed (centred on P in Fig. 1), where a late upfold brings up a core of Central Highland Division rocks within the Grampian group in the form of a tectonic window⁷. In this window, at least three very early generations of structures can be recognised, each associated with high-grade metamorphism. The earliest of these is a regional gneissosity. The second takes the form of penetrative isoclinal folding of this gneissosity, associated with migmatization and a high degree of mobilisation. The third forms a large regional recumbent fold which refolds the earlier structures.

The rocks of the Grampian group do not share these structures: they young consistently upwards for more than 1.5 km above their tectonic base, and lack intensive folding. Their earliest folds are associated with cover-basement sliding which truncates, shears out and superimposes new foliations on the early structures in the underlying basement. This contrast in the structural and metamorphic complexity between the Central Highland Division and the Grampian group is best interpreted in terms of an older basement separated by sliding from a younger cover.

In this Grampian group, the schistosity (S1) of the earliest deformation, D1, is highly overprinted by the effects of a major

event, D2. S1 can only be seen where it is folded around the hinges of F2 folds, and no F1 folds have been found. D2 resulted in a regional schistosity subparallel to the bedding, accompanied by kyanite-grade amphibolite facies metamorphism and by sliding in the cover-basement contact zone, where D2 fabrics are those of coarse, platy-tectonic schists.

A subsequent major event, D3, resulted in a new regional schistosity associated with lower grade amphibolite facies metamorphism and renewed sliding in the Grampian Slide zone. D3 sliding was associated with the growth of a penetrative fabric of replacement muscovite in the movement zones. In the tectonic schists, the D3 overprint of D2 produced platy muscovitic D3 fabrics, in which D2 fabrics are granulated and aluminosilicates are retrogressed. Subsequent deformations will be described elsewhere.

In this region, the D2-D3 Grampian Slide forms a zone 30-200 m thick, in which both basement and cover rocks are variably tectonised into tectonic schists, and in which tectonic slices of basement are present in the cover rocks.

In this slide zone a distinctive suite of concordant-sub-concordant foliated pegmatite veins occurs at localities as far as 60 km distant⁷. The pegmatite veins, 1 cm to 7 m thick, are present in both tectonised basement and cover rocks. They do not appear above or below the slide zone, and are interpreted as a syntectonic suite emplaced into movement zones. Rb-Sr analyses of 10 muscovite samples from five foliated pegmatites in the Dulnain watershed (Fig. 1) yield a grouping of ages within the range 718 $\pm$ 19 Myr to 573 $\pm$ 13 Myr (Table 1). The spectrum of ages in individual pegmatites corresponds with field distribution of D2 and D3 strains in the rocks of the slide zone. The higher ages are from pegmatites which share well preserved D2 slide-fabrics with surrounding tectonised rocks. Conversely, the lower ages come from pegmatites in zones more thoroughly modified by the later D3 fabrics.

This limited spread of ages indicates that the age of pegmatite emplacement into the movement zone, and the age of the D2 sliding, are unlikely to be much older than 718 $\pm$ 19 Myr. Thus, the pegmatites and the D2 event correspond with the Morarian ages of pegmatites in the western Moine region⁵. The same age pattern also implies that the D3 event which partly resets the radiometric clocks in retrogressive metamorphic conditions accompanied by liberal fluid activity, is younger than 573 $\pm$ 13 Myr, and is therefore clearly Caledonian.

It follows that the cover rocks of this region—rocks belonging to the lower part of the Grampian group—are older than the Morarian pegmatites. Correspondingly, as already indicated, the Grampian group cover is believed to be younger than the Central Highland Division basement. We tentatively correlate the latter with the strikingly similar Glenfinnan Division rocks from which the Grenvillian (1,030 $\pm$ 50 Myr) migmatitic

Granitic Gneiss of Ardour (Fig. 1) is thought to have developed *in situ*^{6,7,14}.

Viewed in this light, the D1–D2 events in the Grampian group fall within the Grenvillian–Caledonian interval, and are considered here to signify the reality of a limited orogenic event of Morarian age (broadly between 750 and 850 Myr) within the Moines (see ref. 5). Additional support for such a Morarian event comes from recent Rb–Sr whole-rock analyses of large samples of semipelites from the north-east Ox Mountains and Lough Derg inliers in western Ireland. These data yield an 860 ± 115 Myr isochron and indicate a post-Grenvillian maximum age (M. B. Max and C. D. Long, personal communication).

Field and radiometric evidence therefore indicate that at least the lower part of the Grampian group represents sedimentation during the Grenvillian–Morarian interval, and that its rocks were affected first by the Morarian event, and subsequently by the Caledonian orogeny. These rocks are referred to informally as being of Morarian age.

This model poses the problem of a Morarian–Caledonian interval, the nature of which remains unresolved. The metasediments of the uppermost part of the Grampian group are reported to pass into the overlying Dalradian by a sedimentary transition^{3,10,11}, whereas in some areas tectonic contacts intervene between the two^{2,7,12}. Apart from sections near its tectonic base⁷ and others adjacent to the Dalradian^{3,10,11}, much of the Grampian group still awaits detailed examination. It may be significant that in the Grampian group west of Loch Erich, Thomas¹³ reports the presence of an older and a younger series of metasediments separated by a major slide.

West of the Great Glen Fault, in the Loch Eil Division^{1,2}, the rocks along and to the south of Loch Eil appear to closely match certain formations of the Grampian group in their lithologies, sedimentary structures and in their apparent degree of structural–metamorphic complexity. In the region of Glen Tarbert, the rocks match those of the Central Highland Division^{7,14}.

Nearer to the Moine Thrust, a case has been made for a Grenvillian age for the early metamorphism and deformation in the Morar Division^{15,16}. However, there is now mounting evidence^{5,14} that the Precambrian event in these rocks may have been the Morarian event, and that they may be broadly equivalent in age to the Torridonian sediments deposited on the foreland between 1,000 and 800 Myr (ref. 17)—a long standing correlation¹⁸. This Morar Division is separated from the almost certainly Grenvillian (see ref. 6) rocks of the Glenfinnan Division by a major break, the Sgurr Beag Slide (Fig. 1). If the Morar Division is indeed of Morarian age, then the Sgurr Beag Slide assumes a similar structural position in separating Grenvillian basement from Morarian cover, as the Grampian Slide east of the Great Glen Fault.

The lower part (at least) of the Grampian group, probably parts of the Loch Eil Division, the Morar Division, the Tarakavaig Moines (Fig. 1)—already correlated with the Torridonian Sleat Group¹⁷—and the rocks of the north-east Ox Mountains and Lough Derg inliers of Ireland, may all form parts of one major assemblage, to which the arkosic Torridonian of the foreland would also belong. Such an assemblage is regarded as being analogous to a combination of groups which, as has yet to be demonstrated in the field, may make up a Moine Supergroup of Morarian age.

A Caledonian blueschist from the Irish Dalradian

THE occurrence of the blue amphiboles glaucophane and crossite in metamorphosed basic rocks is characteristic of terranes metamorphosed at high pressures. Most examples are from relatively recent fold belts. We record here a Caledonian blueschist from the Dalradian Supergroup in South Achill Island, County Mayo (Fig. 1). It is the first 'old' blueschist from Britain to occur in a regularly bedded and folded sequence and may imply an early high pressure metamorphic event in this part of the Dalradian, evidence for which was generally destroyed by either erosion or later metamorphism.

The blueschist outcrops on Claggan Beach, 0.75 km south-west of Ashleam Bay (Fig. 1). The rocks exposed on the beach are mostly metasediments. Psammites predominate on the north side with interbedded pelitic schists, while metabasites occur on the south side. The metabasites are predominantly albite–epidote–chlorite schists but contain epidosite pods a few tens of cm in diameter and a more continuous boudinaged epidosite layer about 1 m thick that contains crossite and is therefore referred to as a blueschist.

The geology of the area has been described elsewhere^{1–3}. The basic rocks have been ascribed to the Upper Dalradian by Harris and Pitcher⁴ but a Middle Dalradian age has been recently proposed by Max and Long⁵.

The blueschist is fine grained (0.1–0.2 mm) and predominantly composed of epidote that is typically near $\text{Ca}_{2.08}\text{Fe}_{1.01}\text{Al}_{2.12}\text{Si}_{3.11}$ (calculated from microprobe analyses on an anhydrous basis) but with up to 2.30 Al atoms at some analysed points. Crossite occurs throughout the rock but is also concentrated into thin layers visible in hand specimens. Crossite compositions range from $\text{Na}_{1.88}\text{Ca}_{0.15}\text{Fe}_{2.02}^{\text{tot}}\text{Mg}_{2.28}\text{Al}_{0.80}\text{Si}_{8.20}$ to $\text{Na}_{1.92}\text{Ca}_{0.07}\text{Fe}_{1.51}^{\text{tot}}\text{Mg}_{2.12}\text{Al}_{1.36}\text{Si}_{8.15}$, tending to be richer in glaucophane at the margins. The rock also contains quartz, albite (>99% Ab) and hematite, with small granules of sphene sometimes associated with the hematite. Quartz and albite tend to occur together in felsic segregations, and crossite occurs both with these phases and in regions of epidote only.

Crossite grains often show marginal alteration to finer grained amphiboles, especially where quartz, albite and hematite are also present. Crossites enclosed in epidote are often unaltered. Two distinct alteration products are recognised, but there may be some gradation between them. They are a bright green barroisitic amphibole which usually replaces crossite directly, and a colourless to pale green actinolite that may mantle either the crossite or the barroisite. Microprobe analysis of these alteration products is difficult because of their fine grain size, but the barroisite in particular seems to be of rather variable composition. One point gave $\text{Na}_{1.54}\text{K}_{0.02}\text{Ca}_{0.65}\text{Fe}_{2.06}^{\text{tot}}\text{Mg}_{2.30}$

$Mn_{0.02} Al_{1.18} Ti_{0.01} Si_{7.69}$. The actinolite is rich in Na and Al, near $Na_{0.47} Ca_{1.55} Fe_{1.49} Mg_{3.29} Mn_{0.01} Al_{0.70} Ti_{0.02} Si_{7.67}$.

Crossite has not been found in separate smaller epidosite pods on the same beach, but the barroisitic and actinolitic amphiboles are both present and show similar mutual relationships. Stilpnomelane is also present in some of these smaller pods. We infer from these observations that crossite formed early in the metamorphic history of the rock and subsequently became unstable.

Crossite schists of this type are typical of many high pressure metamorphic belts throughout the world⁶ and, in the absence of jadeite and lawsonite, are probably best assigned to a high pressure greenschist sub-facies rather than the glaucophane schist facies. In such terrains the blue amphibole occurs in oxidised metabasites only and this may partly explain its scarcity in the Dalradian.

The Claggan blueschist we describe here is the first to be reported from the Dalradian and it is also the first from the British Caledonides to occur in a regularly bedded and folded sequence; the similar crossite schists at Ballantrae and Anglesey are isolated occurrences in areas of complex, highly faulted geology. It therefore seems that at least this part of the Dalradian underwent an early high pressure metamorphism and the observed breakdown of crossite may reflect a change in conditions towards a conventional Barrovian facies series. The Barrovian regional metamorphic grade in South Achill is very low¹ and it is therefore the most likely part of the Irish Dalradian for early assemblages to be preserved.

Ernst⁷ has documented the variations in blueschist abundances with age and suggests that the scarcity of pre-Mesozoic

blueschists results from changes in the thickness of lithospheric plates with time. Modern blueschist facies assemblages with jadeite, lawsonite or aragonite may not have been stable in the Palaeozoic Earth. However, blueschists may have formed in the past but have been particularly susceptible to destruction during orogeny. England and Richardson⁸ calculate that blueschists will tend to be rather rapidly destroyed by erosion after orogeny. Thus they interpret the scarcity of old blueschists as resulting from the destruction of blueschist belts which were once present. In addition, relaxation of the thermal gradient might destroy high pressure assemblages that remained at depth. The discovery of a crossite schist in the Dalradian may accord with both these theories, but it does provide evidence that traces of former high pressure metamorphism can be very largely destroyed.

Thus in South Achill the moderately high pressure crossite schists, formed early in the Grampian orogeny, were largely destroyed by subsequent metamorphism. It is possible that other blueschists formed from Dalradian and related rocks were uplifted and destroyed by erosion rather than further metamorphism. The evidence for this is the presence of detrital ferroglaucofan and crossite in probable mid-Ordovician rocks of the Longford-Down region recently reported by Sanders and Morris⁹.

We thank Drs P. Treloar and J. V. P. Long for microprobe facilities at Cambridge University. J.F.G. acknowledges receipt of a NERC research studentship.

Direct observation of a free radical interaction between vitamin E and vitamin C

VITAMIN E (α -tocopherol) and vitamin C (ascorbic acid) react rapidly with organic free radicals, and it is widely accepted that the antioxidant properties of these compounds are responsible in part for their biological activity¹⁻⁵. Tissue vitamin C levels are often considerably greater than those of vitamin E, for example in liver the values are approximately 2 mM and 0.02 mM, respectively. Nevertheless, vitamin E is considerably more lipophilic than vitamin C, and in biomembranes has been found to be the more potent antioxidant, particularly with respect to lipid peroxidation; penetration to a precise site in the membrane may be an important feature of the protection against highly reactive radicals⁶. Tappel has suggested that the two vitamins act synergistically, vitamin E acting as the primary antioxidant and the resulting vitamin E radical then reacting with vitamin C to regenerate vitamin E⁷. We now report direct observation of this interaction, which we feel may be an important feature in the maintenance of vitamin E levels in tissues.

As vitamin E is poorly soluble in water, conventional pulse radiolysis techniques, involving aqueous solutions and oxidising radicals such as $OH^\cdot$, cannot be used to generate the related free radical (Vit E[•]). We have shown that the trichloromethylperoxy radical $Cl_3COO^\cdot$ can be generated in aerated water-isopropanol-acetone mixtures containing carbon tetrachloride,

reactions (1)–(5). The radical is a moderately reactive one-electron oxidising agent and has been shown to react with various nucleophilic compounds, with rate constants of the order of 10^7 – 10^8 $M^{-1} s^{-1}$ (ref. 8).

On pulse radiolysis of such a solution containing vitamin E we have observed the formation of a transient species with an absorption spectrum similar to those previously assigned to phenoxy radicals⁹. We attribute the absorption to the radical, Vit E[•]. Free radical scavenging actions by vitamin E have been ascribed to the initial reaction of the phenolic hydroxyl group with the production of a phenoxy radical¹¹. The rate of its formation was first order in vitamin E concentration corresponding to:

$$k = 5 \pm 1 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$$

The absorption decayed over a period of 3 ms. However, in the presence of vitamin C its spectrum changed rapidly, a decrease in absorption at 425 nm occurring simultaneously with an increase at 360 nm. These changes are attributed to the formation of the vitamin C radical (Vit C[•]) in view of previously published data concerning its absorption spectrum^{2–4}:

Figure 1 shows spectra of the transient species present 10 μ s, 400 μ s and 1,600 μ s after an aerated solution containing isopropanol (50%), acetone (10%), carbon tetrachloride (0.04 M), α -tocopherol (3.4×10^{-3} M) and ascorbic acid (1.60×10^{-3} M) neutralised with sodium hydroxide was irradiated with a 0.2- μ s pulse of 4 MeV electrons from the Brunel linear accelerator.

Fig. 1 Absorption spectra at various times after pulse radiolysis of an aerated solution of vitamin E and vitamin C. (—●—) vitamin E[•], (---●---) vitamin C[•], see text.

Fig. 2 Oscillograms obtained at 425 nm (decay of vitamin E[•]) and at 360 nm (grow-in of vitamin C[•]) for the reaction between the vitamin E radical and vitamin C (2.88×10^{-3} M ascorbate). Ordinate, 1% absorption per large division; abscissa, 100 μ s per large division.

After 10 μ s the spectrum is principally that of Vit E[•] with a small contribution (10%) from Vit C[•] whereas after 1,600 μ s the spectrum is that of Vit C[•] alone. Oscillogram traces of the decay of Vit E[•] at 425 nm and the concurrent grow-in of Vit C[•] at 360 nm are shown in Fig. 2 for a similar solution but containing 3.2×10^{-3} M ascorbic acid. Both the decay and the formation of the absorbing species were exponential, with first order rate constants proportional to vitamin C concentration. From measurements at four vitamin C concentrations the rate constant for reaction (7) was $1.55 \pm 0.2 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$.

Such a rapid interaction may well be pertinent to protection from free radical-mediated damage *in vivo*: the recycling of vitamin E at the expense of vitamin C may account in part for the fact that clinically overt vitamin E deficiency has not been demonstrated in man. Moreover in certain conditions the vitamin C radical can itself be enzymatically reduced back to vitamin C by a NADH-dependent system¹⁰. Thus this allows the repair of an otherwise potentially damaging organic free radical R[•] to be linked to NADH oxidation and a wide range of normal biochemical processes.

Opposite cerebral hemispheric superiorities for visual associative processing of emotional facial expressions and objects

STUDIES of patients with unilateral cerebral lesions¹ or surgically disconnected hemispheres² suggest a functional asymmetry in processing visual information by the two hemispheres. The right hemisphere (RH) seems to favour matching of pictures of objects by similarity of shape (apperceptive matching), whereas the left hemisphere (LH) favours matching by similarity of meaning or conceptual category (associative matching). As, on the other hand, considerable recent experimental evidence supports the hypothesis that the RH might have a distinct role in processing emotional information³⁻⁸, it would be surprising if the RH lacked the capacity of associative processing which is important in emotional communication. Using tachistoscopic half-field presentation the present study produces evidence for a RH superiority for associative processing in response to adequate stimuli such as emotional facial expressions, whereas the LH is more efficient in detecting similarity of function between objects whose shapes are very different.

Twenty-four adult right-handed normal subjects (12 men, 12 women, 20-30 yr old) performed two visual half-field experiments. The method was identical in both experiments. Subjects had to fixate a central point in a two-channel tachistoscope. Two pictures were then simultaneously shown to them for 150 ms. One of the pictures, a stylised drawing, was always presented in central vision at the point of fixation. The other, a photograph, was presented to either the left or the right side of the drawing, either in the left or the right visual field (LVF/RVF). With exposure a timer was started. If the subject felt that the two pictures represented the same meaning, he pressed a button to stop the timer, otherwise no response had to be given. Equal numbers of positive and negative instances were presented randomly and equal runs of right and left hand responses were used in alternation. Each subject participated in four sessions, on four different days. A session consisted of 96 projections for each experiment. A total of 384 pairs of pictures per subject and experiment were shown.

Fig. 1 'Happy', an example of a common emotional expression in two faces of different shape. The faces were photographed as close as possible according to the features outlined by Ekman and Friesen⁹. To enhance affectivity, the two persons whose faces were photographed were known to all subjects. The stylised drawing was always presented in central vision, subtended a maximum visual angle of 1.7° on each side of the point of fixation. The photograph of the same size was presented either on the left or the right side of the drawing, within 2.2-5.6° of visual angle from fixation point. The 24 subjects were subdivided into two groups of 12 (6 men, 6 women) to whom photographs were presented with faces or objects orientated to the right or the left respectively. The order of presentation was alternated between the experiments, balanced for sex of subjects and picture orientation.

Fig. 2 'Corkscrew', an example of two different objects belonging to a common category to which

In experiment 1, subjects were presented with pairs of pictures, one representing a stylised drawing of a male or female face in profile, showing the face with an emotional facial expression, that is, 'happy' or 'astonished'. All possible combinations of the two faces and six photographs were used. Variance analysis of correct decisions revealed faster times for LVF than for RVF ($F(1.368) = 15.72$; $P < 0.001$), indicating RH superiority (Fig. 3) and a significant decrease in time in the course of the testing ($F(3.368) = 6.44$; $P < 0.001$), suggesting a 'learning effect'. Differences between hands and interactions did not differ significantly ($P > 0.05$). Neither the sex of the person being tested nor the orientation of faces on the photographs had any significant influence on the difference in times of decision between visual fields. There were 24% errors. Analysis of errors revealed a significant decrease in the course of the testing, independent of visual fields ($F(1.6) = 27.47$; $P < 0.005$). No other differences in errors between visual fields, hands, sex of subjects or orientation of pictures could be found.

In experiment 2, presentation and data analysis were identical to those in experiment 1. Drawings and photographs represented three different categories of objects, that is 'corkscrew' (Fig. 2), 'key' and 'brush'. Times for correct decisions were shorter for RVF than for LVF ($F(1.368) = 11.31$; $P < 0.001$), indicating LH superiority (Fig. 3) and the learning effect was again significant ($F(3.368) = 10.72$; $P < 0.001$). Again there was no significant difference in times of decision between hands and interactions. Neither the sex of subjects nor the orientation of objects on the photographs had an influence on the difference in time between the visual fields. There were 4% errors equally distributed between visual fields, hands, sex of subject and orientation of pictures. No decrease in errors in the course of testing could be found.

The above findings show that associative processing of non-verbal visual information is stimulus dependent and that there is a functional asymmetry of associative processing by the two hemispheres. A possible mechanism, which would very probably favour the LH, could be 'inner verbalisation'. To reduce possible differences in the capability of verbalisation, we used as a reference picture a highly stylised drawing, which allowed easy verbalisation of the emotional facial expression as well as of the object classes. Nevertheless the behaviour of the subjects indicated very different levels of awareness of the correctness of decisions for emotional facial expressions as opposed to object categories. Often, erroneous object judgments were followed by rapid recognition of the errors, whereas for emotional expressions subjects repeatedly expressed the sense of having made an error, when in fact the manual response had been correct. However this is an incidental observation which needs to be explored systematically.

To conclude, we found that visual associative processing is not exclusively a function of the left hemisphere, but that both

Fig. 3 Differences in LVF, thus indicating right hemisphere differences. *a*, Experiment 1 (emotional expression); *b*, Experiment 2 (object).

hemispheres are capable of visual associative performance. There are, however, two different associative procedures: The left hemisphere seems to be superior on an associative task requiring recognition of a common category to which different objects belong, whereas the right hemisphere seems to be superior on an associative visual task requiring recognition of a common emotional facial expression in different faces. Although it is not proven that the emotional feature in the facial expression was critical in producing the right hemisphere superiority, this would be consistent with the recently expressed view, that the RH might have a distinct role in processing emotional information.

Naloxone dose dependently produces analgesia and hyperalgesia in postoperative pain

If endorphins modulate pain, then naloxone should affect pain behaviour even in subjects who have not received exogenous opiates. However, some naloxone studies claim a lack of effect^{1,2}, others a hyperalgesic effect³⁻⁵, and others both hyperalgesic and analgesic effects^{6,7}. Such discrepancies may arise from the different methods used to induce and assess pain⁸, and from variation in dose. We know of only one previous human study which used multiple doses of naloxone⁶; this indicated a dose-dependent bi-directional effect. In the present study, a clinical pain paradigm was used to generate a dose-response curve for naloxone. We report that naloxone produces analgesia at low doses and hyperalgesia at high doses.

The patients studied were 35 males and 42 females, aged 19-32 yr. Detailed methods were published previously⁸. Subjects underwent a standardised surgical procedure for the removal of impacted mandibular third molars after premedication with 10-20 mg of diazepam. During surgery, 15-40% nitrous oxide and local anaesthesia with 3% mepivacaine without vasoconstriction (effective duration 45-75 min, ensuring reversal of anaesthesia before experimental interventions) were used. Naloxone can have effects which are not specific for opiates. In fact, a naloxone interaction with both diazepam^{9,10} and nitrous oxide¹¹ has been reported. However, these interactions are unlikely to have a significant effect on the conclusions of this study for reasons discussed previously⁸.

The patients received placebo as their first medication 2 h after the onset of local anaesthesia. One hour later, naloxone was given double blind in doses of 0 (placebo), 0.4, 2, 7.5 or 10 mg. Patients rated their pain by a mark on a 10-cm horizontal line which had the words 'no pain' at the left (0 cm) end and 'worst pain ever' at the right (10 cm). The validity of this scale has been discussed elsewhere⁸. Pain was measured 5, 20 and 60 min after each injection. The pain at 60 min, the time of greatest placebo effect, was used in the present analysis. Pain, with this paradigm, increases over time. This was demonstrated by administration of placebo by a secret intravenous infusion line so that the patients did not know that they had received anything, and the surgeon did not know what he had administered (a blind placebo)¹². Placebo responders were those subjects in whom pain decreased or was unchanged 1 h after placebo administration. Placebo non-responders were those patients whose pain increased over that hour.

Figure 1 shows dose-response curves for the change in pain and mean pain levels, 1 h after naloxone. For placebo responders, the dose-response curve is bi-directional. Compared with placebo, naloxone at low doses (0.4 and 2 mg) produces analgesia, whereas at higher doses (7.5 and 10 mg) it produces hyperalgesia. The naloxone-induced reduction in pain level is significantly greater than that produced by placebo both at the 0.04 mg dose ($0.01 > P > 0.005$, by the Student *t* test) and at the 2 mg dose ($0.05 > P > 0.025$) of naloxone. At the 7.5 and 10 mg doses, the change in pain is significantly greater than that produced by placebo ($0.05 > P > 0.025$). Figure 1b also demonstrates a bi-directional dose-response curve when pain level, rather than change in pain, is plotted.

When the analysis is carried out for placebo non-responders, naloxone has relatively little effect (Fig. 1a). In fact, if all non-responders are compared with placebo (0 mg), there is a slight hyperalgesia ($0.1 > P > 0.05$). When responders and non-responders are pooled, the bi-directionality is still apparent (Fig. 1a).

The finding that naloxone has a bi-directional dose-response curve present in placebo responders, may resolve some of the apparent conflict among previous reports. Grevert and

Fig. 1 Dose-response curve for the effect of naloxone on post-operative pain. The change in pain level (*a*) and the mean pain level (*b*), with standard error bars, 1 h after different doses of naloxone, is plotted for the three groups of patients: (1), placebo responders (●); (2), placebo non-responders (○); (3), groups (1) and (2) pooled (◐). Sample sizes for responders and non-responders, respectively, are: 7 and 13 (0 mg); 5 and 10 (0.4 mg); 4 and 6 (2 mg); 6 and 6 (7.5 mg); 7 and 13 (10 mg). The increase in pain following a second placebo (change in pain for responders given 0 mg) represents transition to non-responders in some patients who were responders to the initial placebo, administered 1 h before administration of the dose plotted.

Antiviral effect of interferon by the host in vivo may be mediated by the host

INTERFERON has been shown to act both *in vivo* and *in vitro*. In interferon-treated cells *in vitro* the cycle of the virus is inhibited at the transcriptional level, depending on the virus. Viral replication is also the direct inhibition of viral replication has been the mechanism by which interferon has been shown to be effective *in vivo*. We report here results that show the effect of interferon against viral infection *in vivo* and the inhibition of the viral replication of the same virus in

To test the antiviral effect of human leukocyte interferon (HLI) *in vivo*, six rhesus monkeys were infected intradermally with different doses of vaccinia virus (strain of the Rijks Instituut voor de Volksgezondheid, RIV)² of which three were treated daily with HLI administered intramuscularly. The HLI was prepared as described previously³. The preparation used in these experiments had a specific activity of 2.1×10^6 units per mg protein. In control monkeys the lesions reached their maximum at day 7. Daily intramuscular injections of 5×10^5 units HLI per kg body weight during 8 d completely inhibited the development of the typical vaccinia-induced skin lesions (Fig. 1). No skin lesions were detected during the observation period of 4 weeks following infection. However, we were unable to correlate this distinct *in vivo* effect of HLI with a corresponding inhibition of the cytopathogenic effect (CPE) of the same virus on diploid rhesus monkey skin fibroblasts or on Rous sarcoma virus transformed human fibroblasts (RSb cells). Up to 10^4 units of HLI failed to protect the cells against the CPE of vaccinia virus (RIV strain), although the CPE of vesicular stomatitis virus (VSV) was effectively inhibited (Table 1). Surprisingly, vaccinia virus was resistant to interferon in our *in vitro* system, but the same results were obtained *in vitro* with the vaccinia virus strain WR and with smaller challenge doses (10^{-3} TCID₅₀)⁴. Also no anti-vaccinia activity could be detected in the sera of the monkeys 4 h after the first injection with HLI. At this time, the sera showed the maximum titre of antiviral activity when tested against VSV. Similar experiments performed with human diploid skin fibro-

Fig. 1 *In vivo* effect of human leukocyte interferon (HLI) in rhesus monkeys infected intradermally with vaccinia virus. Monkeys were treated with HLI from day -1 to day 7 at 5×10^5 units kg⁻¹ i.m. They were vaccinated intradermally at day 0 with the following preparations: 10^7 TCID₅₀ ml⁻¹ vaccinia virus (a); 10^6 TCID₅₀ ml⁻¹ vaccinia virus (b); 10^5 TCID₅₀ ml⁻¹ vaccinia virus (c); 10^7 TCID₅₀ ml⁻¹ vaccinia virus, subjected to UV- and heat-inactivation (d); NaCl (e). For each dilution, 0.05 ml were injected at three sites. The vaccination sites 12 d after infection are shown in a rhesus monkey treated with HLI (left) and in a control monkey (right). Three monkeys were treated with interferon and three served as controls.

Table 1 *In vitro* inhibition of the cytopathogenic effect (CPE) of vaccinia virus by human leukocyte interferon (HLI) and serum from rhesus monkeys treated with HLI

Preparation	RSb cells		Skin fibroblasts from rhesus monkeys	
	VSV	Vaccinia virus	VSV	Vaccinia virus
HLI, 10^4 units ml ⁻¹	10,000	<1	10,000	<1
Pre-serum*	<10†	<10	ND	ND
Post-serum*	350†	<10	ND	ND

Rous sarcoma virus transformed human fibroblasts (RSb) or monkey skin fibroblasts were plated in microtitre plates, grown to confluency (4×10^4 cells per well) and treated with serial dilutions of HLI containing 10^4 units per ml of rhesus monkey sera (before and after injection of 5×10^5 units HLI kg⁻¹). After overnight incubation, the supernatant was removed and cells were infected with vesicular stomatitis virus (VSV) or vaccinia virus (multiplicity of infection 0.25 TCID₅₀ per cell). The incubation was terminated when untreated infected control cells showed more than 90% CPE. The cells were stained with crystal violet. Both viruses were always tested simultaneously in the same microtitre plate and an interferon standard preparation was included. The activity of interferon is expressed as the reciprocal of the highest dilution giving 50% protection. The titres are given as reference units (tested against standard preparation 69/19).

* Before and after 4 h after injection of rhesus monkeys with 5×10^5 units of HLI per kg.

† Mean titre of three monkeys. ND, not determined.

blasts and rhesus monkey kidney cells showed identical results. There was also no inhibition of the production of infectious vaccinia virus (unpublished results).

These findings indicate that interferon can be effective *in vivo* against a virus which is insensitive to its antiviral action in various cell types. Likewise, it has been shown by others⁵ that interferon can inhibit *in vivo* the growth of tumour cells which are resistant to its growth inhibitory action *in vitro*. Interferon may activate several defence systems of the host, for example, the cytotoxicity of the natural killer cells and the macrophages^{6,7}. Perhaps such 'aggressive' cells can selectively destroy virus-infected cells *in vivo*.

Thrombin and epidermal growth factor become linked to cell surface receptors during mitogenic stimulation

THERE is much evidence that interaction with specific cell surface receptors is a key event in the action of polypeptide hormones and growth factors. Many analyses of hormone-receptor interactions have been carried out based on the assumption that hormone binding to the cell receptors is a reversible reaction¹⁻³. Indeed, many studies have demonstrated that bound hormones dissociate from their receptors. However, in most systems the possibility could not be excluded that a significant fraction of the hormone molecules that bind to cells become linked to their receptors. Our present studies with the polypeptide mitogens ¹²⁵I-thrombin and ¹²⁵I-epidermal growth factor (¹²⁵I-EGF) show that a significant percentage of the

Fig. 1 Linkage of ¹²⁵I-EGF to cell receptors. *a*, Cultures were rinsed with DV medium containing 15 mM hydroxyethyl-*N,N'*-piperazine sulphonate, pH 7.3 (DV HEPES medium), and incubated for 1 h at 37 °C with 3 ml DV HEPES medium containing 0.1% bovine serum albumin (BSA) and either ¹²⁵I-EGF (10 ng ml⁻¹) (●) or ¹²⁵I-EGF plus 2 μg ml⁻¹ unlabelled EGF (○). The cultures were rinsed six times with 2 ml ice-cold phosphate-buffered saline (PBS) and the cells solubilised in 0.2 ml 0.1 M Tris buffer (pH 6.8) containing 3% SDS, 1% 2-mercaptoethanol, 2.0 mM phenylmethylsulphonyl fluoride and 0.6% *N*-ethylmaleimide. The samples were incubated in a boiling water bath for 5 min and applied to disc gels containing 5–20% linear polyacrylamide gradients and 0.1% SDS. The gels were cut into 2-mm slices, dried, and the radioactivity measured with a γ-counter. The arrow indicates the 170–190 K component. *b*, The experiment described in *a* was carried out using ¹²⁵I-EGF at the indicated concentrations. The radioactivity in the bands was corrected for nonspecific binding by subtracting the radioactivity bound in the presence of 2 μg ml⁻¹ unlabelled EGF. ○, c.p.m. in the 170–190 K component (EGF-R); △, total specifically bound radioactivity (c.p.m. in EGF-R plus c.p.m. in unlinked ¹²⁵I-EGF).

Fig. 2 Time courses of formation and degradation of EGF-R. *a*, As described in Fig. 1*a*, HF cells were incubated with ¹²⁵I-EGF (20 ng ml⁻¹) for various periods, rinsed, solubilised and heated. Samples (20 μl) and red blood cell marker proteins were applied to slab gels containing a 5–20% linear polyacrylamide gradient and 0.1% SDS. The gels were fixed, stained with Coomassie blue, and dried. Autoradiographs were produced using Kodak XOMAT R film. Lanes 1–4 show the results of incubating cells with ¹²⁵I-EGF for 10, 60, 180 and 420 min, respectively. *b*, HF cell cultures were incubated with ¹²⁵I-EGF (20 ng ml⁻¹) as described in Fig. 1*a*, and were quickly rinsed six times with ice-cold PBS. The cultures were reincubated at 37 °C with 3 ml DV HEPES medium for various periods. The cells were then rinsed twice with ice-cold PBS, solubilised and heated as described in Fig. 1*a*. SDS-PAGE and autoradiography were carried out as described in *a*. Lanes 1–4 show 0, 60, 120 and 180 min incubations, respectively, following removal of ¹²⁵I-EGF-containing medium.

molecules that are specifically bound on human fibroblasts become linked to cell surface receptors. This finding has broad implications for the way in which these molecules might stimulate cell division. It also raises the question of whether linkage of polypeptide hormones to their receptors is a general phenomenon.

Human foreskin (HF) cells (passage 7–11) were grown in Falcon tissue culture dishes containing Dulbecco–Vogt modified Eagle's medium (DV medium) and 5% calf serum as previously described⁴. Cells for experiments were seeded in 60-mm dishes at 3×10^4 cells per cm², and were incubated in serum-containing medium for 3 d, then in serum-free medium for 2 d. EGF was purified by the method of Savage and Cohen⁵. EGF⁶ and thrombin⁷ were iodinated by published procedures. Both proteins contained an average of 0.7 I-atoms per molecule. SDS-polyacrylamide gel electrophoresis (SDS-PAGE) using disc and slab gels was carried out by the method of Laemmli.⁸

We have recently used the procedures of Das and Fox to radiolabel the EGF receptors on HF cells with ¹²⁵I-EGF-NAPEDE, a photoactivable cross-linking derivative of ¹²⁵I-EGF⁹. We found that the EGF-receptor complex had a molecular weight (MW) similar to the 190,000 dalton (190 K) EGF-receptor complex reported in mouse cells¹⁰. During this work, we discovered that some of these receptors also became labelled by ¹²⁵I-EGF that lacked a photoactivable group. Figure 1*a* shows the distribution of radioactivity in gel slices after SDS-PAGE of solubilised HF cells that had been incubated with ¹²⁵I-EGF (10 ng ml⁻¹) for 60 min at 37 °C. In this and the following experiments, the cells were solubilised by boiling in 3% SDS and 1% 2-mercaptoethanol, conditions that disrupt noncovalent interactions between most proteins. As shown, about 90% of the radioactivity was found in a rapidly migrating band. We identified this material as ¹²⁵I-EGF on the basis of its MW (about 6,000). In addition, 6–9% of the radioactivity specifically bound to the cells was contained in a 170–190 K component. This component was absent when a vast excess of unlabelled EGF was present in the binding medium to reduce interaction of ¹²⁵I-EGF with its receptors (Fig. 1*a*), or when ¹²⁵I-EGF was incubated without cells. These results showed that a significant fraction of bound ¹²⁵I-EGF became directly linked to cellular receptors for EGF. This linkage was probably

covalent because the labelled 170–190 K component survived treatment with 6 M guanidine-HCl and 0.1 M 2-mercapto-ethanol¹¹.

The amount of ^{125}I -EGF that became linked to receptors (EGF-R) increased with increasing concentrations of ^{125}I -EGF and was maximal at 40 ng ml^{-1} ^{125}I -EGF (Fig. 1b). This was about the same concentration dependence displayed by total specific ^{125}I -EGF binding. Thus, at all ^{125}I -EGF concentrations examined, linked ^{125}I -EGF accounted for a relatively constant fraction (6–9%) of the total specifically bound ^{125}I -EGF. Also, the amount of EGF-R varied with duration of ^{125}I -EGF incubation roughly in parallel with total specific ^{125}I -EGF binding. Figure 2a (lane 1) shows that EGF-R and also ^{125}I -EGF specifically bound but not linked (EGF) were apparent after only 10 min incubation at 37°C . The amounts of both EGF-R and EGF continued to increase during the first hour of incubation with ^{125}I -EGF (lane 2), but decreased markedly during the next few hours (lanes 3 and 4). The decrease in ^{125}I -EGF binding that occurs during several hours of incubation with ^{125}I -EGF is caused by a decrease in the number of EGF receptors (down regulation)^{12,13}. Apparently, the receptors that were linked to ^{125}I -EGF were down-regulated with the other EGF receptors.

The rate at which ^{125}I -EGF became linked to receptors suggested that this reaction took place at the cell surface. Consistent with this view, EGF-R formed during a 10-min incubation with ^{125}I -EGF was completely removed by a 10-min treatment with trypsin ($10\text{ }\mu\text{g ml}^{-1}$) at 37°C . However, after a

Fig. 3 Linkage of ^{125}I -thrombin to cell receptors. *a*, Cultures were incubated at 37°C for 20 min with DV HEPES medium, and the medium was replaced with DV HEPES medium containing 0.5% BSA and either ^{125}I -thrombin ($0.25\text{ }\mu\text{g ml}^{-1}$) (●) or ^{125}I -thrombin plus $5\text{ }\mu\text{g ml}^{-1}$ unlabelled thrombin (□). The cultures were then incubated for 90 min at 37°C and rinsed, solubilised and heated as described in Fig. 1a. The samples were applied to disc gels containing 7.5–15% polyacrylamide linear gradients and 0.1% SDS. The radioactivity in gel slices was determined as described in Fig. 1a. The arrow indicates the 65K component. Unlinked ^{125}I -thrombin migrated in gel slices 34–37. *b*, The experiment described in *a* was carried out with ^{125}I -thrombin at the indicated concentrations. The radioactivity in the 65K and unlinked ^{125}I -thrombin bands were corrected for nonspecific binding by subtracting the radioactivity that bound in the presence of $5\text{ }\mu\text{g ml}^{-1}$ unlabelled thrombin. □, Radioactivity in the 65K component and bound but unlinked ^{125}I -thrombin; ●, c.p.m. in the 65K component.

Fig. 4 Time courses of the formation and disappearance of Th-R. *a*, Using the procedures described in Fig. 3a, HF cells were incubated with ^{125}I -thrombin (50 ng ml^{-1}) for various periods at 37°C , and prepared for SDS-PAGE as described in Fig. 1a. Samples were applied to slab gels containing 5–20% linear polyacrylamide gradients and 0.1% SDS, and autoradiographs were made. Lanes 1–8 show the results of 20 s, 40 s, 80 s, 160 s, 9 min, 30 min, 60 min and 90 min incubations, respectively. Lane 9 shows the result of a 30-min incubation with ^{125}I -thrombin when $8\text{ }\mu\text{g ml}^{-1}$ unlabelled thrombin was present. *b*, Cultures incubated with 50 ng ml^{-1} ^{125}I -thrombin for 90 min were quickly rinsed six times with 2 ml ice-cold PBS, and incubated for various periods at 37°C with 3 ml DV HEPES medium containing $8\text{ }\mu\text{g ml}^{-1}$ unlabelled thrombin. The cells were then rinsed twice with cold PBS and processed for SDS-PAGE as described in Fig. 1a. The samples were applied to slab gels containing 7.5–15% linear polyacrylamide gradients and 0.1% SDS, and an autoradiograph was prepared. Lanes 1–6 show the results of 0, 10, 30, 270 and 360 min incubations, respectively, following removal of ^{125}I -thrombin-containing medium. In lane 6 cultures were treated as in lane 4, except that the ^{125}I -thrombin incubation was carried out in the presence of $8\text{ }\mu\text{g ml}^{-1}$ unlabelled thrombin.

1-h incubation with ^{125}I -EGF, most of the EGF-R was insensitive to trypsin, suggesting that it had entered the cells. During ^{125}I -EGF incubations longer than 1 h, iodinated components of approximate MWs 70,000, 50,000 and 36,000 appeared (Fig. 2a, lanes 3, 4). Figure 2b shows that these resulted from processing or degradation of EGF-R. When cultures incubated with ^{125}I -EGF were rinsed and incubated at 37°C with medium containing no EGF, the unlinked ^{125}I -EGF disappeared from the cells within 1–2 h, but much of the EGF-R remained (Fig. 2b, lanes 1–3). During the next 2 h, most of the EGF-R was degraded to a component of MW 36,000, and additional products of 70,000 and 50,000 MWs (Fig. 2b, lanes 3, 4). Degradation of EGF-R occurred more rapidly if EGF was present in the medium. Similar results have been obtained in studies with mouse cells in which the fate of the EGF receptor covalently linked to ^{125}I -EGF through a photoactivated cross-linking reagent was studied^{9,10}.

These results with EGF prompted us to determine whether thrombin, another highly purified growth factor for HF cells¹⁴, also became linked to its receptors during mitogenic stimulation. Fibroblasts possess a large number of specific high-affinity thrombin receptors (about 2×10^5 receptors per cell with a K_d of 1×10^{-9} M in mouse cells)¹⁵. Binding to these receptors is apparently necessary for thrombin-stimulated cell division¹⁵. When HF cells were exposed to ¹²⁵I-thrombin ($0.25 \mu\text{g ml}^{-1}$) for 90 min at 37 °C, most of the specifically bound radioactivity migrated with material larger than ¹²⁵I-thrombin, and about one-third of the specifically bound radioactivity was linked in a well defined complex of MW 65,000 (65 K component) (Fig. 3a). Because the MW of thrombin after reduction is about 30,000 (ref. 16), this indicated linkage to a receptor of about 35,000. (However, these MWs are only rough estimates, as thrombin is a glycoprotein.) The remainder of the specifically bound radioactivity migrated with free thrombin and heterogeneous material that was smaller than the 65K cross-linked complex but larger than thrombin. As with EGF-R, the ¹²⁵I-thrombin-receptor complex (Th-R) survived treatment with 3% SDS and 1% 2-mercaptoethanol in a boiling water bath for 5 min, suggesting that this linkage is also covalent. The Th-R probably resulted from interaction of ¹²⁵I-thrombin with cell receptors because it was absent either when ¹²⁵I-thrombin was incubated without cells (data not shown), or when a vast excess of unlabelled thrombin was added to inhibit interaction of ¹²⁵I-thrombin with its receptors (Fig. 3a).

Cellular formation of Th-R was apparent at a thrombin concentration of 2 ng ml^{-1} , and approached a maximum at $0.4 \mu\text{g ml}^{-1}$ ¹²⁵I-thrombin. The concentration dependence of Th-R formation and total specific ¹²⁵I-thrombin binding exhibited a similar concentration dependence (Fig. 3b). Interestingly, the dose dependence of thrombin for stimulation of HF cell DNA synthesis approximately corresponds to that for Th-R formation (unpublished results), consistent with the possibility that Th-R transmits the mitogenic signal.

Formation of Th-R by HF cells incubated with ¹²⁵I-thrombin at 37 °C could be detected within 20 s, and reached steady-state within 30 min (Fig. 4a). In contrast, the amount of bound but unlinked ¹²⁵I-thrombin (Th) increased more slowly. The rapidity of Th-R formation suggested that this linkage occurred at the cell surface. This was confirmed by the finding that a 10-min treatment with trypsin ($10 \mu\text{g ml}^{-1}$) at 37 °C removed Th-R formed after a 3-min incubation of cells with ¹²⁵I-thrombin. After a 90 min binding incubation most of the Th-R was insensitive to trypsin, suggesting that it had been internalised. We found no evidence of discrete degradation fragments from Th-R. When cultures incubated with ¹²⁵I-thrombin were rinsed and incubated at 37 °C with medium containing unlabelled thrombin, Th-R gradually disappeared over 4 h without the appearance of other bands (Fig. 4b).

We have reported here a novel interaction of human cells with two protein mitogens, EGF and thrombin. Both molecules became linked to their specific cell surface receptors, both linkages seemed to be covalent, and in both cases the coupled growth factor-receptor complexes apparently entered the cells. These linkages were not caused merely by transfer of ¹²⁵I from the growth factors to receptors, as chymotryptic digestion of EGF-R and Th-R released polypeptide fragments of ¹²⁵I-EGF and ¹²⁵I-thrombin, respectively.

The finding that polypeptide factors become linked to cell surface receptors is unexpected but not inconsistent with current knowledge. The direct linkage of EGF to cell surface receptors of normal and transformed murine cells and isolated membranes has been found simultaneously by Linsley *et al.* and is reported in the accompanying paper¹⁷. Insulin and trypsin have also been reported to become tightly associated with cell components^{18,19}, although it is unclear from these reports whether these associations survive treatment with SDS. In studies on the interaction of ¹²⁵I-insulin with H-4 hepatoma cells, a significant quantity of what seems to be an insulin-receptor complex (MW 120–130,000) was found, and was resistant to treatment with

SDS and 2-mercaptoethanol (C. Hoffman and D. F. Steiner, personal communication). Direct linkage of polypeptide hormones and growth factors to cell surface receptors might be a general phenomenon which will facilitate both the identification of these receptors and study of their metabolic fate. The role of polypeptide-cell surface receptor complexes in the action of these polypeptides remains to be studied. However, Shechter *et al.* recently concluded that the growth stimulatory effects of EGF "may be mediated by occupation of only a negligible fraction of very high-affinity binding sites" (ref. 20). The present data are consistent with the possibility that this "very high-affinity" binding represents EGF-R.

We thank Dr John W. Fenton, II for gifts of highly purified human thrombin, and Tom Ho for technical help. This research was supported by a grant from the NCI. J.B.B. and K.C.G. were supported by training grants from the USPHS. D.D.C. was supported by a Research Career Development Award from the NCI.

Direct linkage of epidermal growth factor to its receptor

EPIDERMAL GROWTH FACTOR (EGF), a potent polypeptide mitogen, has been studied intensively by those concerned with the molecular events leading to cell proliferation^{1–4}. The initial, reversible interaction of EGF with a specific cell surface receptor and the subsequent internalisation and degradation of EGF, and by inference the EGF-receptor complex, are well documented, although the role of these events in mitogenesis is unknown^{4–6}. In an attempt to define this role, we used photoaffinity probes to specifically cross-link radiolabelled EGF to its receptor, a 185,000-dalton polypeptide on the surface of murine 3T3 cells⁷. These probes also enabled us to follow the metabolic fate of this receptor⁸. We have since noted that a small portion of the underivatized radiolabelled EGF that binds specifically to 3T3 cells or isolated 3T3 cell membranes becomes directly and irreversibly linked to a polypeptide of molecular weight (MW) 185,000. Here, we document this association and

show that the resulting complex has properties identical to those of the EGF-receptor complex originally identified by photo-affinity labelling.

When 3T3 cells were incubated with ^{125}I -EGF, and the proteins solubilised in ionic detergent solution and subjected to electrophoresis, 1–2% of the specifically bound label migrated as a band of apparent MW 190,000 (Fig. 1, lane A). The radioactivity in this band was reduced when unlabelled EGF was included with labelled EGF in the binding medium (Fig. 1, lanes C, E), an indication that the appearance of the 190,000 MW band requires specific binding of EGF.

EGF resembles certain other hormones in its capacity to reduce the number of available specific receptor sites when incubated with cultured cells^{3–6,8}. This ligand-induced reduction of binding activity is termed 'down regulation', and in the case of the EGF receptor, occurs by internalisation of the receptor protein⁸. When 3T3 cells were treated with unlabelled EGF to down-regulate the EGF receptor before addition of labelled EGF, formation of the direct linkage complex was greatly reduced (Fig. 1, lane G), a further indication that complex formation requires EGF specific binding. Also, when cells were incubated with labelled EGF for longer periods, radioactivity disappeared from the 190,000 MW direct linkage complex and appeared in the same three degradation products that are formed during down-regulation of the photoaffinity-labelled EGF-receptor complex (Fig. 1, lanes B, D, F)⁸. These data show that a small amount of the ^{125}I -radioactivity in specifically bound EGF becomes directly linked with its receptor.

Fig. 1 Formation of the direct linkage complex and the derived metabolic products during down-regulation. Monolayer cultures of Swiss mouse 3T3 cells (clone 42) were grown on plastic dishes, as previously described⁷. Confluent cultures were washed three times with binding medium (DMEM, without NaHCO_3 but containing 10 mM HEPES and 1.0 mg ml⁻¹ bovine serum albumin). Some samples were incubated with 50 ng ml⁻¹ unlabelled EGF for 4 h at 37 °C to allow for down regulation of receptor. All samples were incubated for 30 min at 37 °C with iodinated EGF⁷, at 50 ng ml⁻¹ (1.5×10^3 c.p.m. per ng) in binding medium, and excess unlabelled EGF was added where noted. The ^{125}I -EGF preparations used contained 0.5–1.0 atoms of iodine per mol of EGF. The cells were washed to remove unbound labelled EGF, then incubated in binding medium at 37 °C for the indicated times, washed again, frozen, thawed and dissolved in electrophoresis sample buffer (ESB: 63 mM Tris, pH 6.8, 3% SDS and 10% glycerol). Aliquots of 100 μl of each sample were subjected to electrophoresis on a 10% acrylamide gel, using the discontinuous system of Laemmli¹¹. On completion of electrophoresis, the slabs were stained with Coomassie blue, destained, dried on filter paper, and autoradiographed on X-ray film (Kodak no screen NS-2T). The band of radioactively labelled material visible at the interface between the stacking and resolving gels in this experiment is not present when samples are boiled or subjected to shear forces before electrophoresis, conditions which do not quantitatively alter the amount of radioactivity present in the receptor band. (A) Formation of the direct linkage complex (R) by incubation of cells with ^{125}I -EGF for 30 min at 37 °C. (B) Formation of receptor degradation products (I, II and III) when samples from (A) were incubated in binding medium for an additional 30 min at 37 °C. (C) As (B), but with 500 ng ml⁻¹ of unlabelled EGF present during ^{125}I -EGF binding. (D) as (B), but with 60 rather than 30 min of additional incubation. (E) as (D), but with 500 ng ml⁻¹ unlabelled EGF present during ^{125}I -EGF binding. (F) As (B), but with 120 rather than 30 min of additional incubation. (G) Cells were incubated with 50 ng ml⁻¹ of unlabelled EGF for 4 h at 37 °C to down regulate the EGF receptor before ^{125}I -EGF binding.

Fig. 2 Immune precipitation of specifically bound EGF and the EGF-receptor direct linkage complex. ^{125}I -EGF was bound to cells for 60 min at 23 °C as described in Fig. 1. After washing to remove unbound EGF, the cells from three 78-cm² dishes were scraped into binding medium and sedimented in a Brinkman microfuge. The cells were vigorously mixed for 2 min with 0.9 ml of 0.5% (v/v) Triton X-100 in binding medium and then incubated for an additional 10 min at 23 °C. Insoluble material was removed by sedimentation for 2 min in a microfuge; more than 90% of the cell-bound radioactivity and the bulk of the direct linkage complex remained in the supernatant fraction. Determination of immune precipitable total cell-bound EGF (O): 100 μl of the supernatant fraction were mixed with 10 μl of binding medium containing the indicated amounts of unlabelled EGF. To this, 10 μl of binding medium containing 1 μg of IgG fraction¹² of rabbit anti-EGF¹³ were added and the samples incubated for 30 min at 4 °C, after which, 10 μl of 10% (v/v) solution of formalin-fixed *Staphylococcus aureus*, an immune adsorbent¹⁴, were added. After a 15-min incubation at 4 °C, the immune adsorbent was sedimented for 2 min in a microfuge and the radioactivity present in the pellet and supernatant fractions measured to determine the per cent of total radioactivity which adhered to the immunoadsorbent. Determination of immune precipitable EGF-receptor direct linkage complex (Δ). Each pellet and supernatant fraction from the immunoadsorption experiment was treated to achieve the stated concentrations of the components in ESB, boiled and centrifuged to remove the immune adsorbent. Samples were subject to electrophoresis on a 10% acrylamide slab¹¹, and the region of the gel containing the direct linkage complex excised for measurement of radioactivity.

As direct linkage could result from transfer of labelled iodine from ^{125}I -EGF to its receptor, we used an antiserum specific for EGF to determine the immunoreactivity of the labelled 190,000 MW protein in non-ionic detergent extracts (Fig. 2). The bulk of the radioactivity initially present in both total cell-associated EGF and in the direct linkage complex was immune precipitated by antiserum to EGF. Also, unlabelled EGF similarly inhibited the precipitation of both the direct linkage complex and total cell-associated EGF. This last observation shows that much of the direct linkage complex consists of a single immunoreactive EGF molecule in stable association

Table 1 Time course of ^{125}I -EGF binding and direct linkage complex formation with a cell surface membrane preparation

	Incubation temperature (°C)	Incubation time (h)	
		1	2
Total binding (c.p.m.)	0	1,658	1,546
	23	3,547	2,777
	37	3,602	2,686
Direct linkage complex (c.p.m.)	0	10	49
	23	21	112
	37	43	120

3T3 cells were grown to confluence on 3,400 cm² of surface area in Dulbecco's modified Eagle's medium (DMEM) + 10% fetal calf serum (FCS) for preparation of cell surface membranes¹⁶. Particulate fractions banding at less than 40% (w:w) sucrose were pooled and collected by sedimentation. The membranes were suspended in binding medium and divided into three aliquots of 1.0 ml; 0.11 ml of ^{125}I -EGF (2.1×10^5 c.p.m. per ng, 500 ng ml⁻¹) in binding medium was added to each tube for incubation at 0, 23 or 37 °C. Incubations were terminated by layering a 0.1-ml aliquot from each tube above a 1 ml cushion of 10% (w:w) sucrose in binding medium and sedimenting for 2 min in a Brinkman microfuge. The pellets were washed with 1.5 ml binding medium. Total binding was corrected for background binding measured at zero time and was approximately 90% specific. The radioactivity in direct linkage complex was measured as described in Fig. 1 and was also corrected for background binding.

with its high MW receptor protein. However, this does not eliminate the possibility that the direct linkage complex forms through attachment of receptor to an artefactual and highly reactive EGF species produced during radioiodination. We therefore repeated the experiment described in Fig. 2 using unlabelled EGF and cells labelled metabolically with ^{35}S -methionine. Using these cells we identified a high MW ^{35}S -labelled protein band with electrophoretic mobility identical to that of the ^{125}I -EGF receptor direct linkage complex and which was only formed in cells incubated with EGF (data not shown).

Two independent experiments show that the photoaffinity-labelled EGF-receptor complex is degraded in the lysosomes⁸: the degradation products co-fractionate with lysosomal enzyme markers during organelle fractionation, and the degradation of the photoaffinity complex is inhibited by the lysosomotropic drug, chloroquine⁹. The degradation of the direct linkage complex is also markedly inhibited by chloroquine (Fig. 3a), and the rates of degradation (Fig. 3b) in the presence and absence of chloroquine are similar to those previously determined for the photoaffinity-labelled complex⁸.

Fig. 3 a, Degradation of the direct linkage complex and inhibition of degradation by chloroquine. The conditions are essentially those described in Figs 1 and 2. Binding was for 1 h at 23 °C, following binding, and before preparation for electrophoresis, the cultures were incubated at 37 °C for an additional 75 min. The X-ray films were scanned with a densitometer, and the tracings are reproduced. —, Degradation of the direct linkage complex (C) into the proteolysis products characteristic of the EGF-receptor cross-linked complex. C' is a high MW product (142,000) that accumulates in the presence of chloroquine⁹. Bands I, II and III have apparent MWs of 59,000, 38,000 and 30,000 in this particular gel system. ———, Inhibition of direct linkage complex processing by chloroquine. Conditions were as described for Figs 1 and 2. Chloroquine (0.1 mM) was added 15 min before EGF and was present throughout the experiment. b, Effects of prior treatment with chloroquine on the rate of degradation of the direct linkage complex. Conditions were the same as in a, except that chloroquine was added 1 h before EGF. At the indicated times, samples were prepared for electrophoresis, which was carried out on a 10% acrylamide slab. The direct linkage complex was located on the dried gel by autoradiography. The amount of radioactivity present as direct linkage complex at an indicated time of incubation is expressed as a % of the amount of complex present before incubation. ●, No chloroquine added; ▲, plus 0.1 mM chloroquine.

Fig. 4 Correlation between the concentration dependence of EGF binding and direct-addition complex formation. Cells grown as described in Fig. 1 were incubated for an additional day in DMEM plus 0.8% FCS. The cells were washed with binding medium, and total binding was determined at 23 °C after a 65-min incubation with iodinated EGF (2.3×10^4 c.p.m. per ng) at 3.75, 7.5, 37.5 and 75 ng ml⁻¹. Nonspecific binding was measured on duplicate cultures in the presence of 1 μg ml⁻¹ unlabelled EGF. Cultures were washed to remove unbound EGF and the samples were solubilised with 0.1 ml ESB and quantitatively transferred for determination of cell-bound radioactivity. Specifically bound EGF (○) was calculated by subtracting nonspecifically bound EGF from the total amount bound. The resulting binding data were plotted according to Scatchard²⁵, the slope of the curve is thus proportional to the K_A of binding. The samples were then processed for electrophoresis as in Fig. 1. The regions containing the direct linkage complex were excised from the dried gel and total radioactivity was corrected for the nonspecific radioactivity remaining when 1 μg ml⁻¹ unlabelled EGF was present. The specific radioactivity in the complex at a particular EGF concentration was calculated as the fraction of the total radioactivity applied at that concentration (Δ). Each point is the average of two determinations, except for the point at 75 ng ml⁻¹ EGF, which is the average of four determinations. For broken line, —slope = $K_{\text{formation}} = 0.112 \text{ nm}^{-1}$; for solid line, —slope = $K_A = 0.201 \text{ nm}^{-1}$.

If the direct linkage EGF-receptor complex is a complex of EGF and its physiological receptor, the saturability for reversible EGF binding and direct complex formation should be similar. The observed concentration dependence for complex formation, $K_{\text{formation}}$, closely approximated the equilibrium binding constant, K_A , for EGF and its physiological receptor in the intact cell (Fig. 4 and data not shown). Table 1, which shows that complex formation is a slower process than binding, may partly explain the slight discrepancy between $K_{\text{formation}}$ and K_A . This should be accentuated at lower EGF concentrations, where longer periods of time are required to achieve binding equilibrium. Accordingly, the apparent $K_{\text{formation}}$ is an underestimate of its true value. Table 1 also shows that complex formation is more sensitive to a temperature decrease than is binding, and indicates why direct linkage of EGF to its receptor was not observed in our earlier studies with ^{125}I -EGF photoaffinity probes^{7,8}. A comparison of the times and temperatures of exposure to EGF to receptor for direct labelling (Table 1) with those used in the photoaffinity labelling studies^{7,8} shows that direct complex formation would account for less than 10% of the cross-linked complex formed on photolysis^{7,8}.

Thus, we have demonstrated that a small fraction of the EGF specifically bound to its cell surface receptor becomes strongly and directly linked to a high MW protein. This complex and the photoaffinity-labelled EGF-receptor complex have the same biological fate. The biological and chemical properties of the complex, described above are those expected of a covalently linked EGF-receptor complex.

We are now investigating the chemical nature and mechanisms of formation of the complex. Its members are not joined by a disulphide bond—it is not dissociated by boiling in 5% 2-mercaptoethanol. Its formation does not seem to be catalysed by a transglutaminase reaction similar to that responsible for intermolecular protein cross-linking in the red blood cell¹⁰—complex formation is not increased by Ca^{2+} ion, or decreased by added amines such as histamine, glycine ethyl ester or cystamine. Alkylation of the amino terminus of EGF with

biotin¹⁷ did not affect EGF binding, but substantially inhibited direct complex formation, implicating a site on or near the amino terminus of EGF in direct complex formation.

We also have evidence for an EGF-receptor complex in SV40-transformed 3T3 cells, normal human fibroblasts and a human tumour cell line (A-431)^{5,18}; it is also formed when EGF is incubated with human placental membranes. Baker *et al.* (see accompanying paper) have independently detected a EGF-receptor complex in cultured human fibroblasts and have evidence of complex formation between thrombin and its receptor in human foreskin fibroblasts¹⁹. Recently, a complex of insulin and a protein of MW approximately 120,000–130,000 was detected in cultured H-4 cells incubated with ¹²⁵I-insulin; this complex resists dissociation in SDS and accounts for at least 10% of the insulin which binds specifically to these cells (C. Hoffman and D. Steiner, personal communication). A high MW form of ¹²⁵I-insulin, accounting for at least 10% of the radioactivity specifically bound to adipocytes, was detected by Kahn and Baird²⁰; this passes through Sephadex G-50 at the void volume in aqueous solution containing 0.1% Triton X-100, 4 M urea and 1 M acetic acid. We have incubated 1 nM ¹²⁵I-insulin with cultured L1-3T3 cells either before or after they differentiated to form adipocytes²¹ and find a substantial quantity of a component of MW 125,000 ± 5,000 which resists dissociation to form free insulin during 5 min of boiling in aqueous 3% SDS (Iwata, K. and C.F.F., unpublished observation). Taken together, these observations indicate that the direct linkage phenomenon may be a general one, a correlation between the high affinity specific binding of many polypeptide ligands and their cell surface receptors.

Although a biological role for direct linkage of hormones to their specific receptors has not been shown, Schechter *et al.* have concluded that a small fraction of "very high affinity binding sites"—possibly identical to the direct complex—may play a role disproportionate to their fraction of the whole in mediating EGF action²².

Is stimulation of benzodiazepine receptor binding mediated by a novel GABA receptor?

A STEREOSPECIFIC, saturable, high affinity binding site for ³H-diazepam has recently been characterised in membrane fractions isolated from the brains of mammals¹, including man², which has been suggested to represent the pharmacological benzodiazepine (BZ) receptor^{2–4}. Electrophysiological⁵ and biochemical⁶ results indicate that BZs exert their main actions in the central nervous system by facilitation of the synaptic action of γ -aminobutyric acid (GABA). Evidence for an interaction between GABA and BZs at the receptor level has recently been obtained^{7–11}. Thus, GABA has been shown to stimulate BZ binding^{8–11} and there is preliminary evidence that this process is mediated by a specific GABA recognition site, as the GABA agonists muscimol⁸, imidazoleacetic acid¹¹, and 3-guanidino-propionic acid¹¹ also stimulate ³H-diazepam binding. We now report different structural requirements for stimulation of ³H-diazepam binding to rat brain synaptic membranes compared with those for inhibition of Na⁺-independent ³H-GABA binding¹². We suggest that stimulation by GABA of BZ receptor binding involves a novel type of a GABA receptor.

Specific BZ receptor binding was determined with previously frozen and extensively washed membrane fractions from rat brain cerebral cortex with 1 nM ³H-diazepam as labelled ligand¹¹. Specific binding of 5.8 nM ³H-GABA to Triton X-100-treated membranes⁷ was measured using a centrifugation assay¹³.

The structural analogues of GABA in Fig. 1 were examined as stimulators of ³H-diazepam binding. In general, the concentrations of GABA analogues required for 50% activation of ³H-diazepam binding (EC₅₀) were higher than those required for 50% inhibition of Na⁺-independent ³H-GABA binding (IC₅₀). A comparison of the ratios EC₅₀:IC₅₀ revealed remarkable differences. Dihydromuscimol, GABA, and 4-amino-3-hydroxybutyric acid, relatively flexible molecules which can adopt a variety of conformations, exhibited the lowest ratios. Muscimol, thiomuscimol, and *trans*-4-aminocrotonic acid, although still flexible molecules but compounds with partially flattened structures, displayed relatively higher affinities for Na⁺-independent ³H-GABA binding sites. Compounds with even more rigid and flattened structures such as isoguvacine and 4,5,6,7-tetrahydroisoxazolo(4,5-c)pyridin-3-ol (THIP) had very little effect on ³H-diazepam binding but were potent inhibitors of Na⁺-independent ³H-GABA binding. On the other hand, isoguvacine and THIP did not display properties of (partial) antagonists as they failed to modify the submaximal stimulation of ³H-diazepam binding induced by 3 μ M GABA or by 1 μ M muscimol (data not shown). These results point to the existence of a distinct GABA recognition site associated with the BZ receptor, as the structural requirements for the activation of BZ receptor binding are different from those for inhibition of Na⁺-independent ³H-GABA binding.

On extending some previous work^{8,9,11} we found that the effects of all GABA analogues which stimulated ³H-diazepam binding could be antagonised by low concentrations of ($\pm$)-bicuculline-methiodide (10 μ M). In contrast, picrotoxin (30 μ M) had no significant effects on basal or GABA-stimulated ³H-diazepam binding.

The proposed new GABA recognition site is different from the GABA high affinity uptake site as well as the Na⁺-independent ³H-GABA binding site, as potent GABA uptake inhibitors such as guvacine, β -alanine and nipecotic acid^{14,15} had no effect on ³H-diazepam binding. In contrast to Na⁺-dependent ³H-GABA binding, stimulation of ³H-diazepam binding was antagonised by bicuculline-methiodide, enhanced by freezing and thawing¹¹ and insensitive to pretreatment of the membranes with phospholipase A⁹.

Compound	Formula	Activation of ^3H -Diazepam binding EC ₅₀ (μM)	Inhibition of ^3H -GABA binding IC ₅₀ (μM)	EC ₅₀ IC ₅₀
(RS)-4,5-Dihydro-muscimol		0.22	0.041	5.4
Muscimol		0.35	0.015	23
GABA		1.15	0.14	8.2
trans-4-Amino-crotonic acid		1.15	0.060	19
Thiomuscimol		1.50	0.15	10
(RS)-4-Amino-3-hydroxy-butyric acid		17.8	2.60	6.9
3-Guanidino-propionic acid		71.0	3.50	20
Imidazola-acetic acid		89.0	1.20	74
Homomuscimol		280	8.0	36
Isoguvacine		>300	0.45	>500
THIP		>300	0.80	>500
Guvacine		>300	>100	—
(RS)-Nipeccotic acid		>300	>100	—
Gabaculine		>300	>100	—

In conclusion, stimulation of ^3H -diazepam binding seems to be the result of a specific interaction of GABA-like drugs with a novel type or different functional state of a GABA receptor. The distinct structural requirements for stimulation of BZ receptor binding might allow the development of new GABA agonists with selective therapeutic actions.

Fig. 1 Stimulation of ^3H -diazepam binding and inhibition of Na^+ -independent ^3H -GABA binding by GABA analogues. Crude synaptic membranes isolated from rat cerebral cortex were frozen at -20°C for at least 18 h and then washed 5 times by rehomogenisation in 40 vol 50 mM Tris-HCl buffer (pH 7.4)¹¹. Specific ^3H -diazepam binding was determined in triplicates as previously described¹¹. The incubation medium contained membranes (about 250 μg of protein), 1.0 nM ^3H -diazepam in 100 mM Tris-HCl buffer pH 7.4 plus compounds to be tested. At the end of the incubation period (0 $^\circ\text{C}$, 90 min) 5 ml ice-cold buffer (50 mM Tris-HCl, pH 7.4) was added immediately and membranes with bound ^3H -diazepam were trapped on Whatman GF/B glassfibre filters. The filters were instantly washed with additional 5 ml ice cold buffer and specific binding was determined after subtraction of unspecific binding in the presence of excess (3 μM) unlabelled diazepam. In the presence of a saturating concentration of GABA (30 μM) ^3H -diazepam binding was stimulated between 81 and 128% over basal binding. The test compounds were used in at least four concentrations. The following compounds structurally related to GABA (not listed in Table 1) were examined at 100 μM concentration and found to be inactive (less than 10% stimulation) in stimulating specific ^3H -diazepam binding: glycine, taurine, glutamic acid, homocarnosine, baclofen, aminooxyacetic acid, γ -vinyl GABA, γ -acetylenic GABA, δ -aminovaleric acid; 5-amino-valerianic acid and β -alanine were weak activators with EC₅₀ values $>100 \mu\text{M}$. For the determination of specific ^3H -GABA binding crude synaptic membranes from rat cerebral cortex were frozen at -20°C for at least 24 h and treated for 30 min at 37°C with 0.01% Triton X-100⁷. After centrifugation at 40,000g for 15 min the pellet was dispersed with an Ultra-Turrax in 50 vol 50 mM Tris-citrate buffer (pH 7.1) without Triton X-100. This centrifugation was repeated twice. For specific ^3H -GABA binding¹³ aliquots of membranes were incubated in quadruplicate at 4°C for 5 min in 0.5 ml 50 mM Tris citrate buffer (pH 7.1) containing 5.8 nM ^3H -GABA, alone, or in the presence of 4 mM GABA, or in the presence of at least four concentrations of compounds to be tested. After incubation, the reaction was terminated by centrifugation for 10 min at 40,000g. The supernatant was discarded, the pellet rapidly rinsed with cold H_2O and dissolved in NCS (Amersham) solubiliser before counting. The a.c.i.m.s of ^3H -GABA or ^3H -diazepam binding measurements at a single drug concentration were less than 4%. IC₅₀ and EC₅₀ values were determined from log-probit concentration curves and were reproducible within $\pm 15\%$ of the values given (Means of 2-4 separate determinations).

Regulation of muscle acetylcholine receptor synthesis *in vitro* by cyclic nucleotide derivatives

STRONG evidence indicates that muscle activity represses the synthesis of extra-synaptic acetylcholine receptor (AChR) in vertebrate skeletal muscle—(1) electrical stimulation of adult denervated muscle prevents the development of acetylcholine supersensitivity^{1,2} and blocks the incorporation of radiolabelled amino acids into the AChR protein³; (2) *in vitro*, electrical stimulation of embryonic myotubes also causes a decrease in the rate of AChR synthesis; moreover, the abolition of the spontaneous contraction of the myotubes by tetrodotoxin (TTX)

leads to an increase of newly synthesised receptor molecules⁴⁻⁶; (3) chronic paralysis of the neuromuscular junction by cholinergic antagonists increases the synthesis of extrasynaptic AChR in adult and embryonic myofibre⁷⁻⁹. In addition, it has been claimed that 'trophic' factors other than the neurotransmitter acetylcholine¹⁰⁻¹⁴ regulate the level of extrasynaptic AChR. We show here that the synthesis of AChR in cultured embryonic myotubes is modified by cyclic nucleotide derivatives, and we suggest that cyclic nucleotides may serve as intracellular signals¹⁵ in both activity-mediated and neurotrophic control of extrasynaptic AChR synthesis.

Myoblasts were obtained from the hind limbs of 11-d-old chick embryos by mechanical dissociation¹⁶, seeded in gelatin-coated plastic dishes and cultivated in a 3:1 mixture of Dulbecco's modified Eagle's medium and medium 199 (Gibco) containing 10% horse serum (Gibco) and 1% chick embryo extract¹⁷. From 48 to 96 h of culture, the cells were treated with 10^{-5} M cytosine arabinoside to minimise fibroblast proliferation¹⁸. After the second day, the media were changed daily. For the quantitation of cell surface AChR sites, the myotubes were labelled with 10 nM ^{125} I- α -bungarotoxin for 1 h at 37°C, washed three times with phosphate-buffered saline, solubilised in 1 M NaOH containing 1% Triton X-100, and the ^{125} I-radioactivity bound per culture dish was determined in a γ -counter. All toxin binding data were corrected for nonspecific binding determined in the presence of 10^{-5} M decamethonium (always below 3% of total binding).

Addition of the membrane depolarising agent veratridine¹⁹ to myotubes from 7-d-old cultures significantly decreased the

number of α -bungarotoxin binding sites per culture dish to below control levels (Fig. 1). In the same conditions, and in agreement with other authors⁴⁻⁶, blocking of the myotube electrical activity by TTX increased α -toxin binding. Up to the third or fourth day in culture, veratridine and TTX (data not shown) had little effect on AChR accumulation; presumably, at that stage the cells have not developed action potential sodium channels sensitive to these compounds.

In 2- and 7-d-old cultures, dibutyryl cyclic GMP decreased, whereas dibutyryl cyclic AMP and prostaglandin E₁ (PGE₁) increased the number of α -bungarotoxin binding sites per culture dish (Fig. 1). On the other hand, 4×10^{-4} M butyrate had little if any effect on AChR expression (Table 1). Thus, the effect of dibutyryl cyclic nucleotides is nucleotide specific.

Figure 2 shows the concentration dependence of the inhibiting action of dibutyryl cyclic GMP on AChR accumulation; half-maximal inhibition occurred at $\sim 7 \times 10^{-5}$ M dibutyryl cyclic GMP. On the other hand, the half-maximal increase in α -toxin binding sites caused by dibutyryl cyclic AMP required concentrations of $1.3\text{--}1.5 \times 10^{-4}$ M (data not shown).

Fig. 2 Effect of increasing concentrations of dibutyryl cyclic GMP on the number of α -bungarotoxin binding sites in 4-d-old muscle cell cultures. Muscle cultures prepared as in Fig. 1 were treated with the indicated concentrations of dibutyryl cyclic GMP from 48 to 96 h of culture. ● and ▲, data from different independent experiments. The bars correspond to ± 1 s.e.m. ($n = 3\text{--}4$).

Fig. 1 Effects of veratridine, TTX, dibutyryl cyclic nucleotides and PGE₁ on the evolution of ^{125} I- α -bungarotoxin binding sites in muscle cultures. Myotubes were seeded at a density of 6×10^5 cells in a large number of 35-mm culture dishes. After 2 and 7 d in culture, the different reagents were added to several independent dishes. At the concentrations used, none of the additions had significant effects on the morphological differentiation of the cells. Culture condition: x, control; ▼, 1.5×10^{-6} M veratridine; ⊗, 10^{-6} M TTX; Δ, 2×10^{-4} M dibutyryl cyclic GMP; ●, 2×10^{-4} M dibutyryl cyclic AMP; ○, 10^{-5} M PGE₁. Each point represents the mean of at least two to three culture dishes.

Two alternative mechanisms may explain the effect of dibutyryl cyclic nucleotides on AChR levels: a change in the rate of AChR synthesis, or a regulation of its rate of degradation. Because of the great stability of the α -bungarotoxin-AChR complex, the degradation of AChR can be followed after pulse-labelling of the myotubes with ^{125} I- α -bungarotoxin, the loss of bound ^{125} I-radioactivity being a measure of intracellular degradation of the AChR protein^{20,21}. Figure 3 shows that dibutyryl cyclic AMP or dibutyryl cyclic GMP do not significantly alter the rate of AChR degradation in cultured muscle cells. Therefore, these cyclic nucleotide derivatives regulate the synthesis of AChR or its insertion into the cytoplasmic membrane.

In another series of experiments, pre-existing AChR sites were blocked with unlabelled α -bungarotoxin and the appearance of new AChR monitored by ^{125} I- α -bungarotoxin binding. When these experiments were carried out using young myotubes (between 2 and 3 d *in vitro*) cultures treated with dibutyryl cyclic GMP bound less and those treated by dibutyryl cyclic AMP or PGE₁ bound more ^{125} I- α -bungarotoxin than the untreated controls (Table 1a). As expected, veratridine had no significant effect. Seven-day-old myotubes produced similar

Table 1 Accumulation of ^{125}I - α -bungarotoxin binding sites after saturation of pre-existing AChR sites with unlabelled α -bungarotoxin

Culture condition	Concentration (M)	^{125}I - α -bungarotoxin bound (c.p.m. $\pm$ s.e.m. per dish)	n
a, 2-d-old muscle cultures			
Control	—	44,778 $\pm$ 3,420	8
Veratridine	1.5×10^{-6}	41,062 $\pm$ 1,396	5
Dibutyryl cyclic GMP	2×10^{-4}	32,413 $\pm$ 2,486	5
Dibutyryl cyclic AMP	2×10^{-4}	56,676 $\pm$ 4,848	5
PGE ₁	10^{-5}	59,333 $\pm$ 591	3
Butyrate	4×10^{-4}	46,536 $\pm$ 4,100	3
b, 7-d-old muscle cultures			
Control	—	15,023 $\pm$ 1,412	7
Veratridine	1.5×10^{-6}	8,688 $\pm$ 1,318	4
TTX	10^{-6}	25,799 $\pm$ 1,624	6
Dibutyryl cyclic GMP	2.5×10^{-4}	7,772 $\pm$ 339	4
Dibutyryl cyclic AMP	2.5×10^{-4}	18,868 $\pm$ 568	4

TTX + dibutyryl cyclic GMP	$10^{-6} + 2.5 \times 10^{-4}$	8,473 $\pm$ 393	5
TTX + dibutyryl cyclic AMP	$10^{-6} + 2.5 \times 10^{-4}$	33,260 $\pm$ 1,676	4
Veratridine + dibutyryl cyclic GMP	$1.5 \times 10^{-6} + 2.5 \times 10^{-4}$	8,001 $\pm$ 588	5
Veratridine + dibutyryl cyclic AMP	$1.5 \times 10^{-6} + 2.5 \times 10^{-4}$	11,155 $\pm$ 847	4
Butyrate	4×10^{-4}	15,978 $\pm$ 1,810	3

A large set of identical embryonic chick muscle cultures was prepared by seeding 6.8×10^5 cells per 35-mm culture dish. After 40 h in culture, α -bungarotoxin was added to one-third of the dishes at a final concentration of $0.2 \mu\text{g ml}^{-1}$, and the cells were incubated at 37°C for 8 h. The medium was then removed, and the cells washed free of unbound α -bungarotoxin. After the addition of fresh medium and the indicated reagents, the cells were cultivated for a further 24 h before the determination of ^{125}I - α -bungarotoxin binding. The remaining cultures were grown for 7 d and then subjected to the same experimental protocol as described above for the 2 d-old cells. n, Number of culture dishes.

results, except that veratridine became almost as potent as dibutyryl cyclic GMP in reducing the appearance of new surface α -bungarotoxin sites (Table 1b). Furthermore, in these spontaneously contracting cells the TTX-induced increase in the appearance of α -bungarotoxin sites was completely abolished by dibutyryl cyclic GMP and partially antagonised by veratridine; in contrast, the combination of veratridine and dibutyryl

cyclic GMP did not lower the number of α -bungarotoxin binding sites below the value observed with dibutyryl cyclic GMP alone. These observations suggest that membrane depolarisation by veratridine and dibutyryl cyclic GMP regulates AChR synthesis through a common intracellular mechanism. On the other hand, the effect of dibutyryl cyclic AMP superimposes on those obtained with both TTX and veratridine, and so probably involves a different regulatory pathway.

Further evidence for different mechanisms of action for dibutyryl cyclic GMP and dibutyryl cyclic AMP comes from measurements of total protein synthesis (Table 2). Veratridine, TTX and dibutyryl cyclic GMP did not significantly modify the incorporation of ^{35}S -methionine into total myotube protein, but dibutyryl cyclic AMP increased the latter by about 30% over control. Thus, the increase of AChR synthesis by this cyclic AMP analogue might be due to a general enhancement of protein synthesis, whereas its blocking by dibutyryl cyclic GMP seems restricted to this particular (or to a few) protein(s).

Our experiments therefore demonstrate that in cultured myotubes, dibutyryl cyclic GMP (1) represses AChR synthesis in a similar fashion to the depolarising drug veratridine, and (2) abolishes the development of 'acetylcholine supersensitivity' induced by TTX. Cyclic GMP therefore seems to be a suitable candidate for the intracellular messenger of the activity-mediated control of extrasynaptic AChR synthesis. Recent experiments by Beam *et al.*²² with invertebrate and vertebrate nerve-muscle preparations have shown that both nerve and direct electrical stimulation raise the content of cyclic GMP in the adult muscle. In invertebrates, the latter process is Ca^{2+} -dependent²². Interestingly, in chick myotubes D-600, a blocker of Ca^{2+} -channels, stimulates AChR synthesis²³. Moreover, experiments carried out with myotubes from a dystrophic strain of mouse indicate that mechanical contraction is not required for the regulation of AChR synthesis²⁴. It is therefore tempting to speculate that the regulation of AChR synthesis by muscle electrical activity involves successively: (1) the opening of TTX- or veratridine-sensitive Na^+ channels causing an entry of Ca^{2+} and therefore an increase of the cytoplasmic Ca^{2+} concentration; (2) the activation of guanylate cyclase by Ca^{2+} (or the inhibition of a phosphodiesterase); (3) the repression of AChR synthesis by cyclic GMP. Thus, both Ca^{2+} and cyclic GMP would correspond to the previously postulated 'shut off' factors¹⁴.

Fig. 3 Loss of ^{125}I - α -bungarotoxin binding sites in muscle cultures treated with dibutyryl cyclic nucleotides. 2-d-old muscle cultures prepared as in Fig. 1 were pretreated for 42–50 h with $2 \times 10^{-4}\text{M}$ dibutyryl cyclic GMP or dibutyryl cyclic AMP, respectively. The treated and parallel control cultures were then labelled by the addition of ^{125}I - α -bungarotoxin to a final concentration of 10 nM . After 1 h at 37°C , the cells were washed free of unbound toxin and cultivated in new medium containing the indicated additions. At different time intervals, duplicate dishes were removed, and the amount of bound ^{125}I - α -bungarotoxin radioactivity was determined. a: ●, Control; ○, $2 \times 10^{-4}\text{M}$ dibutyryl cyclic AMP; b: ●, control; ○, $2 \times 10^{-4}\text{M}$ dibutyryl cyclic GMP.

Table 2 Effect of TTX, veratridine and dibutyryl cyclic nucleotides on protein synthesis of chick embryonic myotubes in culture

Culture condition	Trichloroacetic acid-insoluble radioactivity (c.p.m. per dish $\pm$ s.e.m.)
Control	3,438 $\pm$ 240
Veratridine	3,452 $\pm$ 249
TTX	3,352 $\pm$ 60*
Dibutyryl cyclic GMP	3,428 $\pm$ 98
Dibutyryl cyclic AMP	4,442 $\pm$ 478

7-d-old muscle cultures prepared as described in Table 1 were treated with the above listed reagents for 20 h (concentrations identical to those listed in Table 1b); after 15 h, medium and additions were renewed. Then ^{35} S-methionine was added to the medium to a final concentration of $3 \mu\text{Ci ml}^{-1}$, and incorporation was allowed to proceed for 2 h. The cells were washed twice with phosphate-buffered saline, extracted in 1 M NaOH containing 5 mM L-methionine, and the trichloroacetic acid-insoluble radioactivity in aliquots of the extracts was determined by a glass fibre filter assay procedure. Number of dishes $n = 4$ or 5 except * $n = 2$.

As far as the effect of cyclic AMP and its derivatives is concerned, the following physiological implications might be considered. First, in cultures of myoblasts the level of intracellular cyclic AMP reaches a peak level shortly before fusion²⁵. The activation of adenylate cyclase may thus be essential for the coordinated induction of differentiated functions, including AChR synthesis in post-fusion myotubes²³. Second, our finding that AChR synthesis is regulated by compounds such as PGE₁ which change the intracellular levels of cyclic AMP offers a new approach to the old problem of 'neurotrophic' control of extra-synaptic acetylcholine sensitivity. Many extracellular factors may modulate the intracellular pool of cyclic AMP and thus superimpose on the cyclic GMP-mediated regulation of AChR by myofibre activity. The suppression of ACh supersensitivity by neural factors other than the neurotransmitter may, for example, result from the secretion of substances which inhibit adenylate cyclase (for example, insulin-like molecules) by the respective motor nerve terminals. In any case, the modulation of AChR levels by changes in the intracellular concentration of cyclic AMP probably represents a non-selective regulatory mechanism which may be connected with the general differentiation and maintenance of myofibre properties.

We thank Dr J. P. Bourgeois for discussions. Activation of steroid hormone-receptor complexes in intact target cells in physiological conditions

AT physiological temperatures glucocorticoids^{1–5}, in common with other steroid hormones⁶, initially interact with normal target cells such as the rat thymocyte by forming hormone-receptor complexes that seem first to be located in the cytoplasm and then rapidly become bound to the nucleus. At low temperatures (0–4 °C) the hormones, when incubated either with target cells or with cytosols from such cells, form 'non-activated' complexes that do not bind to nuclei; subsequent warming of the cells^{1–5}, or of the cytosols together with nuclei^{2,7–11}, leads to the formation of nuclear-bound complexes. As shown originally with oestrogens¹² and later with glucocorticoids^{2,7–18,13}, if cytosols with non-activated complexes formed at 0–4 °C are warmed to 20–37 °C in the absence of nuclei, the complexes become 'activated', and will then bind to nuclei even at low temperatures. Activation, which can also be brought about by increased ionic strength^{7–9,13}, gel filtration, dilution and other treatments¹⁴, has been studied extensively and is known to be accompanied by several changes other than enhanced affinity for nuclei. For glucocorticoid-receptor complexes the changes include enhanced affinity for DNA^{7,10,13–15} and altered mobility on phosphocellulose¹⁶, DEAE-Sephadex¹⁷ and DEAE-cellulose¹⁸ columns. This last property is the one we have used in our experiments. Despite the many published studies on activation, formation of non-activated complexes and subsequent activation have apparently never been demonstrated in cells or cytosols exposed to steroids at normal body temperatures only. Consequently, it is not known whether non-activated complexes and activation have any significant role in physiological conditions, and at least one well known scheme of steroid hormone action¹⁹ does not include the activation step. It is therefore possible that when steroid hormones bind to cytoplasmic receptors at physiological temperatures they immediately form activated complexes. The results described here show that for glucocorticoids this alternative can be excluded: when these steroids interact with receptors in rat thymus cells at 37 °C they initially form non-activated complexes, and subsequently give rise to activated complexes.

Thymus cells from adrenalectomized rats were prepared and incubated in Krebs-Ringer bicarbonate buffer (0.3–0.4 ml packed cells per ml cell suspension) with radioactive steroids using procedures described elsewhere²⁰. Cytosols containing the cytoplasmic steroid-receptor complexes from these cells were

obtained as supernatants following centrifugation (10 min, 2,000g, 3 °C) of broken-cell preparation obtained by diluting the cell suspensions sixfold in 1.5 mM MgCl₂ at 0–3 °C (refs 4, 5, 21). The MgCl₂ solution contained dextran-coated charcoal to adsorb free steroid^{5,21}. DEAE cellulose columns (0.7 cm diameter, 6 ml bed volume) were prepared with Whatman DE-52 cellulose that had been degassed under vacuum while suspended in 300 mM KH₂PO₄ and then washed with starting buffer (5 mM potassium phosphate, pH 7.4, with 0.5 mM dithiothreitol). All column procedures were carried out at 3 °C. Cytosols were applied as 0.7-ml aliquots. Each column was first eluted with 15 ml starting buffer to remove free steroid. This was followed by a 120-ml linear gradient from 5 mM to 300 mM potassium phosphate (pH 7.4) with 0.5 mM dithiothreitol¹⁸. The eluates were collected in 3-ml fractions, from which aliquots were taken for assay of radioactivity. Recovery in the eluates was 85–100% of applied radioactivity.

Fig. 1 DEAE-cellulose chromatography of cytosols containing predominantly non-activated (a) and activated (b) dexamethasone-receptor complexes. For the non-activated complex a cytosol was prepared from rat thymus cells incubated for 120 min with 7 nM [6,7-³H(N)]dexamethasone (specific activity, 33–40 Ci mmol⁻¹, NEN) at 0 °C, and chromatographed as described in the text. For the activated complex a similar cytosol was chromatographed after warming for 15 min at 25 °C. Numbers on the ordinate give the c.p.m. in the 3-ml fractions. The arrows on the abscissae indicate the start of the gradient elution. The peak to the left of the arrow, which probably consists of free steroid, was eluted with starting buffer.

The results in Fig. 1 on non-activated and activated ³H-dexamethasone-receptor complexes from rat thymus cells confirm and extend the results of Sakaue and Thompson¹⁸ on triamcinolone acetonide-receptor complexes from cytosols of rat liver, thymus and other tissues. As in their experiments the unwarmed cytosol, containing predominantly non-activated complex, gives a major peak on DEAE-cellulose chromatography that is eluted late in the gradient (fractions 31–45; following Sakaue and Thompson, we refer to this peak as Peak II). After warming to 25 °C for 15 min the cytosol gives a major peak eluted early (fractions 8–20; Peak I). The peak eluted with starting buffer (from fraction 0 to the arrow, Fig. 1) probably consists of unbound steroid, as the material in these fractions is adsorbed by dextran-coated charcoal, and in contrast to receptor-bound steroid does not bind to hydroxyapatite²². If the initial incubation with ³H-dexamethasone includes 10⁻⁶ M unlabelled dexamethasone, Peaks I and II disappear and the peak eluted with starting buffer is diminished. Sakaue and Thompson¹⁸ found that the steroid-receptor complex in Peak I binds much more efficiently to nuclei, chromatin and DNA-cellulose than that in Peak II; consistent with this, we have previously found that the complexes in warmed cytosols bind more efficiently to nuclei and DNA-cellulose than those in unwarmed cytosols^{2,15}. Our observations thus support Sakaue and Thompson's conclusion that Peaks I and II, respectively, represent activated and non-activated complexes.

The question of whether non-activated complexes are formed in physiological conditions can therefore be reduced to whether the complex initially formed when thymus cells at 37 °C are exposed to dexamethasone is eluted on DEAE-cellulose columns as the non-activated Peak II or as the activated Peak I.

Fig. 2 Time course of formation of non-activated and activated dexamethasone-receptor complexes in rat thymus cells at 37 °C after addition of ³H-dexamethasone. Rat thymus cells incubated at 37 °C were exposed to ³H-dexamethasone for the times indicated. Incubations were terminated by a sixfold dilution of the cell suspension in 1.5 mM MgCl₂ at 0 °C, after which cytosols were prepared and chromatographed on DEAE-cellulose columns as described in the text. Each time of exposure represents a separate experiment, with free ³H-dexamethasone at concentrations of 50–100 nM. Ordinates and abscissae have the same meaning as in Fig. 1. Activated and non-activated complexes are associated, respectively, with the peaks at fractions 10–20 (Peak I) and 30–50 (Peak II). a, 0.25 min; b, 1 min; c, 2.5 min; d, 5 min; e, 15 min, f, 30 min.

The results in Fig. 2, which we have obtained consistently in several such experiments and have also confirmed using ³H-cortisol, show clearly that the non-activated complex is the first to appear. It is almost the only form present after 0.25 min, but is rapidly replaced over the next few minutes by activated complex and after 30 min is nearly undetectable. Figure 2 gives only the relative amounts of Peak I and Peak II at each time, but we have previously shown that in these conditions total cytoplasmic complex, that is, the sum of Peaks I and II, is formed with a half-time of about 1 min and reaches a fairly steady level by 5 min (ref. 5).

Thus, we conclude that the non-activated complex does have an important role in physiological conditions, apparently serving even at 37 °C as an obligatory intermediate in the initial formation of activated complex. In addition, the experimental approach shown in Fig. 2 provides kinetic and steady-state parameters on receptor transformations in intact cells that must be satisfied by any realistic model of receptor activation. Most models to date have been based on results obtained with cell-free systems. For example, it may be difficult to reconcile our results with a recent model of reversible activation, based on experiments with rat liver cytosols. In these, glucocorticoid-receptor complexes reach equilibrium with approximately equal amounts in the non-activated and activated forms, the latter form assayed by ability to bind to nuclei^{23,24}. In this connection, we have preliminary results suggesting that Peak I contains a minor component with little affinity for DNA-cellulose; we do not yet know whether this component is an experimental artefact or a third normal form of the cytoplasmic complex.

Fig. 1 Schematic representation of starch gel electrophoresis of lysates derived from normal and *P. berghei*-infected mouse erythrocytes and from isolated *P. berghei* parasites. Gels were stained for glutathione reductase (GR) activity with 2,6-dichlorophenol indophenol (DCIP) and 3-(4,5-dimethyl-thiazolyl-2)-2,5-diphenyl tetrazolium (MTT) in the presence of NADPH and GSSG¹³. Simultaneous staining of the other half of the gel with DCIP and MTT in the presence of NADPH but in the absence of GSSG resulted in no detectable staining, confirming that these isozymes represent GR. Note the appearance of a novel isozyme of GR in lysates from isolated parasites. The small amount of residual host cell GR in the latter sample is probably due to contamination of the isolated parasites with trapped host cell cytoplasm.

P. berghei (NYU-2 strain) was maintained in male Swiss White mice as previously described⁷. Blood from heavily infected mice (>70% of red cells infected) was collected after ether anaesthesia by axillary incision and aspiration into heparin. White cells and platelets were removed by filtration through powdered cellulose columns¹⁰. GSH¹¹ and glutathione reductase¹² were assayed as before.

P. berghei infected erythrocytes had more than twice the GSH content of uninfected red cells (Table 1). This difference was not an artefact due to changed size or haemoglobin content of

Dependence of plasmodial glutathione metabolism on the host cell

ONE inherited alteration of human red cell metabolism—quantitative deficiency of the X-linked enzyme glucose-6-phosphate dehydrogenase (G-6-PD)—has attained high frequency in many areas of endemic malaria and may protect against fulminant *Plasmodium falciparum* in some unknown fashion¹⁻⁵. G-6-PD catalyses the first step of the pentose phosphate pathway which provides reduced NADPH necessary for conversion of oxidised to reduced glutathione (GSSG → GSH)⁶. Erythrocytes deficient in G-6-PD are inefficient in generating NADPH and, when exposed to oxidants, lose GSH, accumulate oxidised haemoglobin and are destroyed by the reticuloendothelial system⁶. We hypothesised that, if the malaria parasite were to use red-cell NADPH for parasitic functions, the G-6-PD-deficient erythrocyte might be incapable of maintaining adequate GSH content. This would predispose the cell to premature destruction before the parasite matured, thereby limiting the severity of infection⁷⁻⁹. In exploring this hypothesis, we have investigated factors affecting GSH metabolism in malaria-infected mouse erythrocytes. We find that *P. berghei* malaria may utilise host-cell NADPH for the maintenance of parasite GSH. These observations may help elucidate both the parasite-induced red cell oxidant damage⁷ and the mechanism whereby G-6-PD deficiency protects against fulminant malaria infection.

Fig. 2 Regeneration of GSH in whole erythrocytes previously treated with diamide. Suspension of uninfected and infected erythrocytes, haematocrit approximately 2 volumes per cent, were incubated with 0.25 mM diamide in 0.154 M NaCl for 30 s at 4 °C and washed in 0.154 M NaCl. Diamide-treated cells were resuspended to a haematocrit of approximately 2 volumes per cent in Hank's balance salt solution with 20 mg ml⁻¹ glucose, pH 7.4, with and without 500 μM methylene blue. Results are expressed as per cent of initial GSH concentration and represent the mean ± s.e.m. for 11 separate determinations.

infected cells and was apparent whether GSH concentrations were expressed per g haemoglobin, per ml packed red cells (Table 1) or even per 10^{10} red cells (data not shown). Nor was the difference explicable on the basis of decreased red cell age; our *P. berghei* infections last only 5–6 days from inoculation to death with no significant elevations in reticulocyte count.

To explore the possibility that the incremental GSH within infected cells might be parasite rather than erythrocyte GSH, we separated host cell cytoplasm from intact parasites by ammonium chloride lysis¹³. GSH analyses revealed that infected red-cell cytoplasm had normal GSH content, whereas isolated parasites contained most of the GSH found in whole infected cells (Table 1). We then investigated how the glutathione within the parasite might be maintained in the reduced state. Glutathione is constantly being oxidised and the reduction of GSSG to GSH is catalysed by glutathione reductase (GR), for which NADPH is the most important and, perhaps, sole substrate⁶.

Table 1 Concentrations of GSH and activity of glutathione reductase in uninfected and *P. berghei*-infected mouse erythrocytes, and in isolated parasites and host-cell cytoplasm separated by ammonium chloride lysis¹⁴

Group	N	GSH	
		$\mu\text{M per g Hb}$	$\mu\text{M per ml RBC}$
Uninfected red cells	20	5.6 (± 0.2)	1.9 (± 0.1)
Infected red cells	16	16.3 (± 1.5)*	3.9 (± 0.3)*
Group	N	Glutathione reductase (GR)	
		IU per g Hb	IU RBC
Uninfected red cells	15	14.7 (± 0.6)	4.6 (± 0.2)
Infected red cells	11	35.4 (± 4.0)*	7.8 (± 0.5)*
		GSH	GR
		$\mu\text{M per g protein}$	IU per g protein
Isolated parasites	10	12.0 (± 0.4)	15.5 (± 0.7)
Infected red cell cytoplasm	10	5.6 (± 0.3)	20.9 (± 2.3)

Figures in parentheses represent 1 s.e.m. Because the assay which we routinely use for GSH analysis utilizes 5,5-dithiobis(2-nitrobenzoic acid) (DTNB), which may detect other reducing substances, we confirmed the identity of the GSH in infected cells and isolated parasites by chromatography on Biogel P-2 which showed that >95% of the DTNB reacting substance had a molecular weight similar to GSH.

* $P < 0.001$ when compared to values from uninfected red cells (Student's *t* test, two tailed).

Comparison of NADPH-dependent GR activities within uninfected and infected erythrocytes revealed marked increases within infected cells (Table 1). Although some mammalian forms of GR may use NADH as cofactor¹⁴, even at >1 mM NADH we were unable to detect GSSG reduction by either parasite or host cell GR. Starch gel electrophoresis of lysates derived from normal and infected erythrocytes, and from isolated parasites, indicated the presence of a unique parasite GR cathodal to the single host-cell isozyme (Fig. 1). This isozyme of GR in infected red cells is unlikely to be a modified form of the host-cell enzyme because of the large increase in enzyme activity within infected erythrocytes. This increased activity could not be explained by diminished red cell age because, as indicated earlier,

our *P. berghei* infections do not induce reticulocytosis. Furthermore, others have reported similar elevations of both GSH and GR activity in mouse erythrocytes infected with an entirely different species of malaria—*P. vinckei*¹⁶.

However, the source of the NADPH required for the activity of parasite GR was not clear. *P. berghei* (and other forms of malaria), lacks detectable G-6-PD activity^{17–19} and is, therefore, unable to utilise an intact pentose phosphate pathway for the generation of NADPH. Despite this, pentose shunt metabolism is accelerated in parasitised erythrocytes ($5\text{--}10\times$ normal)^{20,21}, although the activity of this pathway is low or absent in the parasite itself¹⁸. These observations suggested that the parasite might be oxidising red cell NADPH, perhaps through NADPH-linked reduction of parasite GSSG. The excess NADP so generated would, predictably, accelerate the host-cell pentose shunt⁶. To test the possibility that parasite GSSG might be reduced by external NADPH, we isolated parasites¹³ and reversibly oxidised parasite GSH to GSSG with diazene-dicarboxylic acid-bis-(*N,N*-dimethylamide) (diamide)²². As shown in Table 2, following brief treatment of parasites with diamide, incubation with exogenous NADPH supports the regeneration of GSH. This GSH regenerated during incubation must occur within the parasite because extensive washing of parasites does not result in a significant decrement in GSH concentration. Note

Table 2 Regeneration of GSH in diamide-treated isolated *P. berghei*

Substrate	Number	GSH, % of initial
None	20	17 (± 6)
NADPH (500 μM)	30	67 (± 14)*
NADPH (50 μM)	6	58 (± 11)*
NADP (500 μM)	8	16 (± 8)
D-Glucose (11 mM)	8	17 (± 4)
G-6-P (500 μM)	6	18 (± 8)
6-PG (500 μM)	6	19 (± 7)
G-6-P (500 μM) + NADP (500 μM)	6	38 (± 12)
6-PG (500 μM) + NADP (500 μM)	6	43 (± 14)

Suspensions of isolated parasites, approximately 10 mg protein per ml, were incubated with 0.7 mM diamide in 0.154 M KCl containing 20 mM Tris buffer, pH 7.4, at 4 °C for 30 min. The parasites were then washed in the KCl-Tris buffer to remove the unreacted diamide and resuspended to a concentration of approximately 25 mg protein per ml in KCl-Tris buffer. GSH determinations were done before and immediately after diamide treatment, and after 60 min incubation with the various additives at 37 °C. In all experiments, the mean of the initial GSH concentrations was $11.2 \pm 0.3 \mu\text{M}$ per g protein and GSH was undetectable immediately following diamide treatment. Results are expressed as per cent of initial GSH and represent the mean ($\pm$ s.e.m.).

* Significantly different from control (no substrate) at $P < 0.001$ by Student's *t* test, two tailed.

that even NADPH concentrations of 5×10^{-5} M (somewhat below the levels found in normal human erythrocytes⁶) will support reduction of intraparasitic GSSG. The failure of the GSH concentration to return to 100% of the initial values is probably due to diamide-induced damage to the parasite as well as possible loss of GSSG during diamide treatment. The glutathione reduction is specific for NADPH; incubation of isolated parasites with glucose, NADP, glucose-6-phosphate (G-6-P), or 6-phosphogluconate (6-PG) results in no reduction of GSSG (Table 2). Samples incubated with both NADP and G-6-P or 6-PG do regenerate some GSH (Table 2), possibly mediated by host-cell G-6-PD and 6-phosphogluconate dehydrogenase which, like other components of host cell cytoplasm, unavoidably contaminate preparations of isolated parasites.

Other observations indicate that the parasite is directly dependent on erythrocyte metabolism for reduction of GSSG.

In diamide-treated intact infected erythrocytes, glucose supports the regeneration of GSH (Fig. 2) within both host-cell cytoplasm and parasite (data not shown). In contrast, similar incubation of diamide-treated isolated parasites with glucose results in negligible reappearance of GSH (Table 2). Finally, parasite GSSG reduction within whole infected erythrocytes also appears to require NADPH. As shown in Fig. 2, methylene blue (which oxidises intracellular NADPH to NADP^{23,24}) blocks GSSG reduction in intact normal and infected erythrocytes incubated with glucose.

The utilisation of exogenous NADPH for the reduction of parasite GSSG to GSH, as well as the inability of isolated parasites to use glucose for this purpose, indicates an intimate metabolic dependence of the parasite upon the host red cell. The attendant oxidation of erythrocyte NADPH during reduction of parasite GSSG may explain both the increased oxidant sensitivity of infected erythrocytes, and the acceleration of pentose shunt activity within infected cells^{21,22}. Our results also suggest a mechanism whereby G-6-PD deficiency may protect against fulminant malaria infection. The utilisation of NADPH by both the host erythrocyte and malaria parasite would overwhelm the limited ability of G-6-PD deficient red cells to regenerate NADPH. The resultant decrement in cellular GSH may predispose the infected erythrocyte to premature, oxidant-induced destruction. Alternatively, the accumulation of GSSG may inhibit parasite protein synthesis²⁵. In either case, the reliance of the malaria parasite on host-cell NADPH may represent a site of action for new antimalarial drugs.

We thank Drs Coy Fitch and J. Haldane for advice and Ms Berger and Ms Roscoe for technical assistance. The investigations were supported by grants from the NIH.

Homogeneous sensitivity of human peripheral blood lymphocytes to radiation-induced chromosome damage

THE routine method for detecting genetic damage induced by environmental agents in man *in vivo* is to examine mitotic cells in short-term peripheral blood lymphocyte cultures for evidence of structural chromosome changes^{1,2}. Chromosome radiosensitivity in lymphocytes irradiated *in vivo* and *in vitro* is similar³, and so dose-response relationships have been established for different qualities and quantities of ionising radiations after *in vitro* exposure of blood samples⁴. These curves are used to estimate doses received in cases of accidental overexposure to radiation^{1,2,5} and in prediction of the sensitivity of human germ cells to heritable radiation damage⁶. Their shape is used to predict the effect of dose rate on chromosome aberration frequencies^{7,8} and to elucidate the mechanisms of induction of

Fig. 1 Metaphase cells at first (a) and second (b) mitosis after exposure of whole blood to 200 rad of X rays, incubation in medium containing BUdR, and harlequin staining¹³. d = dicentric, f = fragment. The harlequin-stained cell in second metaphase carries a dicentric and two identical fragments derived from duplication of a single fragment at first mitosis.

Table 1 Dicentric frequencies and proportions of metaphase cells which have undergone more than one mitosis at different times after irradiation of blood cultures from four donors

Each value is derived from an analysis of 100 cells.

* A significant departure from a Poisson is expected by chance in the total of 22 samples analysed in these experiments

such aberrations⁸. However, accurate dose-response curves can be obtained only if cells are examined for chromosome damage at the first post-irradiation mitosis, because aberrations decline with successive divisions⁹. Crossen and Morgan¹⁰ used the harlequin-staining technique^{10,12} on phytohaemagglutinin (PHA)-stimulated lymphocytes exposed to bromodeoxyuridine (BUdR) to distinguish cells at first and later mitoses *in vitro* (Fig. 1). They have shown that at the conventional sampling time, about 48 h after stimulation, up to 53% of cells may be in second mitosis. Another problem is that the cells examined in first division at 48 h may not be representative of the entire cell population. Several workers¹³⁻¹⁵ have claimed that lymphocytes with different rates of response to PHA stimulation, undergoing first mitosis at different times after stimulation, carry different frequencies of aberrations. They have interpreted this as a sign that lymphocytes in the peripheral blood constitute a heterogeneous population in terms of chromosome radiosensitivity. If this were true, little significance could be attached to the shape of the dose-response curves. We report here that we have used the harlequin technique to show (1) that in spite of radiation-induced mitotic delay¹⁶ high frequencies of cells in second mitosis may still be found at 48 h, and (2) that there is no difference in aberration frequency in first-division cells sampled at various intervals after irradiation. Correct dose-response curves can therefore now be obtained with this method and any sampling time can be used provided that observations are confined to non-harlequin-stained (that is, first division) cells.

In preliminary experiments, X-ray-irradiated or non-irradiated blood samples were cultured in medium containing BUdR

Fig. 2 Proportions of metaphase cells which have undergone more than one mitosis at different times after initiation of cultures of irradiated (150-300 rad of X-rays) or non-irradiated blood. Distinction between cells at first or later mitoses was made after harlequin staining¹² of cells grown in medium (80% Hams F10 + 19% fetal calf serum + 1.0% PHA) containing BUdR at 5 or 10 $\mu\text{g ml}^{-1}$. Cells were exposed to colcemid for 1 h before fixation. Data are from several experiments in which blood from six male donors (aged 21-33 yr) was used. Each point represents the analysis at 100 metaphase cells. Solid and dashed lines have been fitted by eye to the data for BUdR at 10 $\mu\text{g ml}^{-1}$ and 5 $\mu\text{g ml}^{-1}$, respectively. $\circ$, non-irradiated, BUdR 5 $\mu\text{g ml}^{-1}$; ∇ , non-irradiated, BUdR 10 $\mu\text{g ml}^{-1}$; $\triangle$, irradiated, BUdR 5 $\mu\text{g ml}^{-1}$; Δ , irradiated, BUdR 10 $\mu\text{g ml}^{-1}$.

at either 5 or 10 $\mu\text{g ml}^{-1}$, fixed at various times after culture initiation and harlequin stained. After 5 $\mu\text{g ml}^{-1}$, up to 48% of cells were in second mitosis by 48 h (Fig. 2) and 37% even after 300 rad of X rays. BUdR evidently induced some mitotic delay because the frequencies of cells beyond first division (Fig. 2) were, in general, considerably lower after 10 $\mu\text{g ml}^{-1}$ than after 5 $\mu\text{g ml}^{-1}$ (ref. 17). This suggests that in normal culture conditions, without BUdR, there may be even more than 50% of cells at second division by 48 h. Because the magnitude of mitotic delay is dose dependent¹⁶ there will be, at 48 h, a decreasing proportion of cells in second division with increasing dose, which will lead to an exaggeration of the curvature of the dose-response curve when the BUdR method is not used.

Fig. 3 Dicentric frequencies in cells from donor D (see Table 1) at first (●) and second (▲) mitosis after exposure to 200 rad of X rays. Also shown is the proportion of cells at >1st mitosis (×, irradiated; ■, control) at different sampling times.

To investigate aberration frequencies in first-division cells at different sampling times, whole blood from four healthy male donors (aged 21–33 yr) was exposed to 200 rad of X rays (290 kV, 8 mA, 100 rad min⁻¹) at 37 °C, cultured in medium with 10 $\mu\text{g ml}^{-1}$ BUdR, sampled between 40 and 72 h and harlequin stained. Non-irradiated cells were exposed to 10 $\mu\text{g ml}^{-1}$ BUdR or no BUdR, and some irradiated cells were cultured without BUdR. The results are shown in Table 1 and Fig. 3. There was no significant difference between sampling times in aberration (dicentric) frequencies in first-division cells (donor A, first experiment, $\chi^2_4 = 0.79$, $P = 0.90$ – 0.95 ; donor A, second experiment, $\chi^2_3 = 0$, $P = 1.0$; donor B, $\chi^2_3 = 2.46$, $P = 0.70$ – 0.80 ; donor C, $\chi^2_2 = 0.08$, $P = 0.95$ – 0.98 ; donor D, $\chi^2_3 = 0.063$, $P > 0.99$). BUdR did not induce aberrations (compare BUdR treatment with no treatment in Table 1). As in our preliminary studies (Fig. 2), with 10 $\mu\text{g ml}^{-1}$ BUdR the frequency of second divisions at 48 h was low. BUdR did not influence the frequency of aberrations induced by radiation (compare 200 rad only with 200 rad + BUdR at early fixation times before onset of second mitosis). Dicentric frequencies in second-division (harlequin-stained) cells were approximately half those in first-division cells, as expected if (1) 50% of dicentrics form bridges at first anaphase and 50% “fall-free” (ref. 18), and (2) cells with or without dicentrics at first mitosis are equally capable of undergoing second division. The means of the dicentric frequencies at all sampling times in first division cells from donors A (second experiment) B, C and D were similar, being 43.0, 40.3, 44.3 and 42.3 per 100 cells, respectively, but the frequency from donor A in the first experiment (52.4 per 100 cells) was significantly higher than these at the 5% significance level. The reason for this is not clear and repeat samples from the other donors will be required to assess the importance of this observation.

The distribution of dicentrics between first division cells at each fixation time conforms to a Poisson distribution (Table 1).

This provides further evidence of homogeneity of lymphocytes in chromosome radiosensitivity other than the equality of aberration yields in first-division cells at different sampling times.

We thank Miss Ann R. Currie and Mr J. R. Robinson for technical assistance. This research was supported by grants from the Cancer Research Campaign, the MRC and the International Atomic Energy Authority (Contract 1747).

Corrigendum

In the letter ‘Nanosecond transient Raman spectra of photolysed carboxyhaemoglobin’ by K. B. Lyons *et al.*, *Nature* **275**, 565–566 (1978), paragraph 6 line 15 and paragraph 8 line 6 reads 0.002 Å not 0.02 Å. On Fig. 1c 3 cm⁻¹ should read 2 cm⁻¹.

Erratum

The following note in proof should have appeared in the Matters Arising item ‘Synergistic chelation therapy or mixed ligand complexes for plutonium and cadmium poisoning?’ by P. M. May and D. R. Williams, *Nature* **278**, 581; We would like to correct an error in our *Nature* paper⁴. In paragraph 4 and in Fig. 3 legend we reported that tablets of EDTA with salicylate or DNPS (Dimaval) protected mice from acute cadmium poisoning given 1 h post-cadmium. This should have read 5 min rather than 1 h as far as complete survival is concerned. Naturally, complete survival is observed 15 min but not 1 h post-cadmium for a single injection of the combination.

Nature Index and Binders

The complete **Index** for 1977 is available, price £2.50 (U.K.), US\$5.00 (Rest of World). Copies of the 1976 index are still on sale, prices as above.

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

reviews

Physics as natural philosophy

Victor F. Weisskopf

Memoirs of a Physicist in the Atomic Age. By W. M. Elsasser. (Adam Hilger: Bristol, 1978.) \$15.

I HAVE rarely read a memoir of a scientist which is as readable and captivating as this one. Scientists are not usually very good writers, but Walter Elsasser is. My judgement may be biased, as I belong to the same generation of scientists of Jewish origin brought up in the pre-Nazi German environment. The book gives a fascinating and tragic description of his slow and painful recognition as a young man that he did not belong to the society in which he grew up, although its cultural values were deeply ingrained in his thinking and feeling. In some ways he remained German all his life in the sense of Bach, Goethe, Schiller, Beethoven, Helmholtz and Freud. I think this is mainly why Elsasser keeps returning throughout the book to his belief that science should be natural philosophy and not a pragmatic study of nature. He has never felt comfortable in the Anglo-Saxon (or perhaps more typical, American) style of scientific research, although it is not as far from his ideal as he makes out.

In spite of its readability the book has a few shortcomings which will disappoint historians of science. Elsasser was in Göttingen at the time when quantum mechanics was beginning to take shape, but very little can be found in the book of the overwhelming excitement that must have been felt there, or of the discussions between Max Born, Pascual Jordan, James Franck and many others about the foundations of quantum mechanics. Also, too little is said about the enormous influence of Niels Bohr on the development of atomic physics at that time.

Elsasser did not have a happy life. In contrast to many other scientist-refugees, he did not become a full professor at a great university until the very end of his life. He had to work in industrial and governmental laboratories on subjects that were not his own choice, despite the fact that he was the person who initiated important insights into three of the most fundamental problems of physics: the interpretation of the results of the

Elsasser in 1974

Davisson-Kunsman (later Davisson-Germer) experiments as an effect of electron waves; the recognition of a shell-structure in atomic nuclei; the explanation of the Earth's magnetism as a self-generating dynamo in a liquid iron core. All three contributions were published as short notes: they were great flashes of ideas; and it was not Elsasser's style to elaborate details. Indeed, his note on the shell-structure of nuclei was all but forgotten when M. Mayer and H. Jensen rediscovered it 15 years later. They worked it out in detail and received the Nobel prize for their work.

These three contributions of Elsasser should have sufficed to secure him a high position in the scientific community. But he had bad luck all through his life as regards the recognition of his ideas and to his professional career—caused not only by external circumstances but also by his own personality. Elsasser was a difficult and complex character; he describes vividly some of the severe psychological troubles which he encountered in his youth. In spite of all these hardships he never lost his idealism and his devotion to what he calls "conceptual thought"—his interest in the essential and fundamental questions of science rather than in problem solving or empirical data collection.

Perhaps his lack of social success in the scientific community made him supercritical of some personalities and of the character of modern science. He describes the personality of P. Ehrenfest in such dark colours that he is not

recognisable to anyone who had personal contact with this warm-hearted, engaging and stimulating man. It is true that Ehrenfest was sometimes subject to moody periods; obviously a collision happened here between two difficult characters, that prevented Elsasser from recognising the unique humanity and charm of Ehrenfest. Also Hermann Weyl is censured because of his alleged lack of contact with reality in his books on relativity; an accusation which is in no way justified. Homi Bhabha too gets a rather heavy censure when he is accused of "modelling the properties of elementary particles in mathematical terms" and of trying to solve fundamental problems with inadequate means, as many of "those who come from cultures far from the circle of modern Western rationalism". Actually, Bhabha's contributions to particle physics were at least as fundamental as those of any Western physicist.

Elsasser was very much interested in the scientific explanation of the phenomena of life and was very sceptical as to the possibility of a physico-chemical explanation. He wrote three books about the subject, and had to modify his point of view to some extent after the discovery of the DNA double helix. But it is not easy to understand why he found it necessary to denigrate the importance and impact of Schrödinger's pioneering little book *What is Life?*, which has influenced a whole generation of biologists. Elsasser had a very high opinion of Schrödinger in every other respect. But he completely overlooked the fact that Schrödinger introduced for the first time the concept of an "aperiodic crystal", which was later found to exist in the form of DNA. Also, Elsasser seems to assume that the book was written after the discovery of the genetic code.

Altogether the disappointments which Elsasser suffered within the scientific community must have accumulated many prejudices in his thinking. He goes as far as to accuse the life sciences as a whole of being a "denial of science as a creative activity". He says that "scientific research was a process in which observation was related by a reciprocal interaction with thought . . . but now it seemed that in

the life sciences the prevailing approach... has assumed a quite different form"

In physics, he could not approve of the attitude of the younger generation of scientists towards their work: "The modern physics that had emerged... was world apart from the old physics that had for so long been called natural philosophy". Although there may be some truth in what he says about the pragmatic attitude of modern science, his outright condemnation is fundamentally mistaken. The spirit that drives the best of the younger generation—always only the best ones are counted—remains the urge for deeper knowledge and insight into the workings of nature. Maxwell and Darwin would have appreciated modern science if they were still alive.

These exaggerated condemnations do not detract from the intrinsic value of the book. On the contrary, they appear as part of the author's personality and help to bring out the profound predicament of a person brought up in the highly literate and idealistic atmosphere of the well educated central European middle class, when confronted with the spirit (or non-spirit) of the last quarter of our century.

Many episodes during the War are related with great skill. His description of the tensions and problems in F. Joliot-Curie's laboratory during the

German occupation is thoroughly fascinating, as the laboratory served partly as a scientific institution and partly as a centre of the resistance. Unfortunately, he does not mention the heroic role of Professor W. Gentner, who was sent to the laboratory as a German caretaker but, at the risk of his life, kept a helping and protecting hand over Joliot-Curie and his group.

Many deep thoughts and ideas are presented in this book. Elsasser has never shied away from posing the hardest questions and was never discouraged by the difficulties of finding answers. The question of body and mind is often brought up in this book, always illuminating some aspects and indicating the vastness of the problem. Here is one revealing quote: "We tend to look with condescension and pity on that period of history, called the Middle Ages, when men were so concerned with their souls that they often ignored the external world. It seems today that most men are so embroiled in the external world that they have lost sight of the vast dimensions of the world of psyche."

It is a deeply moving book, with some weaknesses, but also with much of the glory that goes with the quest for scientific knowledge. □

Victor F. Weisskopf is Professor of Physics at the Massachusetts Institute of Technology, Cambridge, Massachusetts.

Life from extraterrestrial sources

Colin Pillinger

Lifecloud: The Origin of Life in the Universe. By Fred Hoyle and N. C. Wickramasinghe. Pp. 189 (Dent: London, Toronto and Melbourne, 1978; Harper and Row: New York, 1979) £5.95; \$9.95

OVER the past couple of years a number of articles have appeared in the scientific literature laying the ground work for the Hoyle and Wickramasinghe hypothesis that chemical evolution occurred deep in space in interstellar gas clouds rather than in a 'primeval soup' on the Earth. In the present book they suggest that even very complex biological molecules are produced in this way and contributed to the primitive Earth by cometary impact. They contend that all the comparatively volatile materials in the atmosphere and oceans and even living cells are derived from an extraterrestrial source.

Lifecloud may be summarised as follows. The first three chapters deal with aspects of Darwinian theory. Chapters 4, 5 and 6 provide basic introductions to the functions of cells, the structure of biochemicals and atomic theory, respectively. Chapter 7 discusses how stars are formed, whereas 8 includes a catalogue of the wide range of molecular species in interstellar space now identified by radioastronomy and 9 and 10 are devoted to speculation on the nature of the dust associated with the molecular clouds (mostly the authors' own proposal concerning cellulose). The next two chapters consider the structure of comets and the evidence for biological precursors in meteorites; then come chapters on the birth of the Solar System and the early history of the Earth. Chapters 15 and 16 examine other bodies in our Solar System or associated with the Sun's neighbours as possible abodes for life; Chapter 17 develops the philosophy of the predator in evolution; Chapter 18, entitled "Invasion from the galaxy", is not an appraisal of the much publicised suggestions by the authors that certain epidemic illnesses were brought to Earth by extraterrestrial viruses, but an evaluation of the feasibility of colonising the Universe by space travellers. From the last chapter it is clear that Hoyle and Wickramasinghe favour the armchair

approach of attempting radio communication as an essential first step in exploration.

From the format of the book, it is quite clear that the authors are not writing for specialist readers. The amount of introductory material included suggests that the intended audience may have only a general scientific background. This being the case, in my opinion, the authors should have felt a duty to distinguish clearly what is well founded evidence and what is speculation. Many of their readers will not be equipped to make such a judgement. Bearing in mind that the actual text of the book begins on p 15, and ends on p 174 and the large number of chapters (19) leads to numerous blank or semiblack pages, an attempt has been made to cover an amazing amount of material in probably less than 150 pages. This inevitably means that certain very controversial ideas are presented as fact.

Personally I would have preferred to see a much longer book, more conservatively written and critically reviewing alternatives where they exist. For example, a major theme of the book requires that interstellar dust be identified as cellulose or polysaccharides and spectral evidence is presented to this effect. Most radio astronomers would agree that it is not possible, at present, to decide unambiguously between cellulose and the numerous other materials which have been suggested. Similarly, alternative substances could be responsible for the 2200Å extinction attributed by the authors to $C_6H_5N_3$, but none are discussed. An interesting point, in this respect, is the strength of the evidence required for proof of chemical structure by different scientific disciplines. The organic chemist would consider infrared and ultraviolet spectra, insist on mass spectrometry, like to have nuclear magnetic resonance and attempt coinjection using two gas chromatographic phases. If a natural product was involved its stereochemistry would need to be examined. For some astronomers a near match between comparatively featureless spectra seems to be adequate. Whereas the chemist would concede the difficulties of obtaining data and material for study, perhaps the astronomer could afford to be a little more sceptical. There is a long way to go before the identification of $C_6H_5N_3$ confirms the existence of porphyrins such as $MgC_{48}H_{48}N_4$.

Several instances occur in the book when the evidence presented by the authors needs a much more careful scrutiny than seems to have been the case. On p31, while discussing the possibility of Precambrian microfossils, it is suggested that trace quantities of certain biochemicals have been found associated with the observed structures. No evidence exists to demonstrate that the chemicals in question are due to the microfossils rather than the host rock, whereas strong

Hoyle and Wickramasinghe

arguments favour an interpretation that the samples have been contaminated, not during collection or in the laboratory when great care is taken, but by geological processes. Precambrian rocks contain both classes of compounds and stereoisomers which thermodynamically could not have survived the $1-3 \times 10^9$ yr since rock consolidation. Several groups (for example, Nagy; *Geochim. Cosmochim.* **34**, 525; 1970) were able to show that the porosities of cherts were far in excess of what might be expected, and percolating ground water could easily have transported recently deposited chemical fossils into the Precambrian record.

In examining the clues from meteorites the authors are again guilty of using only selected evidence. The investigation of organic molecules in these extraterrestrial samples are so fraught with controversy that many investigators have declined to study them further. Of the extractable compounds, only the amino acids by virtue of stereochemical arguments may be considered to be indigenous to the samples. Since amino acids are racemic mixtures, it is impossible to decide whether they are biological, that is, associated with meteorite 'microfossils' (assuming you believe these are not organised elements) or the remnants of an abiogenic synthesis. Many of the other classes of compounds which may be extracted by organic solvents from meteorites could be terrestrial contamination. Han *et al.* (*Nature*, **222**, 364; 1969) have shown clearly that easily recognisable amounts of terrestrial organics were accumulated by samples of the carbonaceous chondrite Allende during only a few hours in the terrestrial environment. Like other naturally occurring polymers, the insoluble organic material associated with carbonaceous chondrites is not particularly well characterised despite many heroic efforts. It is generally agreed to be a highly aromatic substance but few would accept an identification as cellulose

on the basis of similarities in the infrared spectrum alone. Perhaps some of the efforts now underway to identify the host phases of isotopically anomalous rare gases in certain meteorites might be more successful in recognising pre-Solar System material. Although a number of possibilities are currently being entertained, cellulose is not among them.

The book contains a number of trivial but real errors. The authors are obviously confused by meteorite terminology. A "fall" is a meteorite observed to fall and later collected; a "find" is a meteorite discovered accidentally and identified as such by its mineralogy, petrology, chemistry etc. Thus (p108) 90% of all "falls" (not finds) are stone meteorites; because of their vulnerability to weathering all known carbonaceous chondrites are "falls" not finds. There are well in excess of 1500 (about 2300) well catalogued meteorites (again not falls) (p 18

and p 108); since the Antarctic bonanza of recent years a great many more samples have been discovered. Many physicists would not agree that the solar wind imprinted the lunar magnetic field (p137). Finally it is to be hoped that the authors' knowledge of chemistry is not accurately reflected by the alarming number of mistakes in the structure of chlorophyll as depicted on p 51 or their choice of glycine (an amino acid without an asymmetric carbon atom) as an example of an optically active molecule (Appendix 2).

Although from my comments it does not seem that I was over impressed with this book, I recommend reading it. I look forward to seeing a revised edition, as I am in agreement with some of the authors' overstated sentiments. □

Acknowledging global links

Peter J. Smith

Cosmos, Earth, and Man: A Short History of the Universe. By P. Cloud. Pp. 372. (Yale University Press: New Haven, Connecticut, and London, 1978.) £10.75.

In his Preface, Preston Cloud thanks "those anonymous critics of the several publishers who rejected an earlier draft of this book for their often cutting but nevertheless helpful comments". It is a gesture of characteristically Cloudian impishness, a humorous rounding-off to a piece of history that lesser people would rather have concealed. But joking apart, things have come to a pretty pass when one of America's best known Earth scientists can build up a collection of rejection slips and then only get published with the aid of a grant. In a market that publishers believe can support more than fifty practically identical general introductions to geology, it is nothing short of disgraceful to find a better book than most of them almost falling by the wayside.

For not only is Cloud a better stylist than most, he has a more original approach to content borne of a more original mind. His line is biogeology, which the American Geological Institute's *Glossary of Geology* defines as the "application of biological data to geology" but which in a lifetime of research Cloud has turned into something altogether more exciting than that dry definition would suggest. The advantage of having a foot in each

of two scientific camps is the acquisition of tendencies to spot connections and perceive correlations between developments parallel in time; and in *Cosmos, Earth, and Man* both are given rein. Where a pure anthropologist might see the ascent of man as a largely isolated phenomenon, Cloud relates man's evolution to the movement of continents, changes in climate and the encroachment of oceans:

"The breakup of the consolidated late Paleozoic continent of Pangaea, followed by the drifting apart of the pieces to form the present continents, set in motion a complex of processes that led to a general moderation of Mesozoic continental climates. Late Mesozoic changes and climatic deterioration that contributed to the extinction of the dinosaurs prepared the way for mammals to inherit the earth. Plate tectonics . . . may be related to the emergence of *Homo sapiens* . . ."

To be sure, our knowledge of global links is sparse and, where it exists, usually rather general. Nevertheless, it stands Cloud in good stead throughout the first three-quarters of his book where he works up from the nature of matter to space and planets, to the origin and evolution of the Earth and atmosphere, and to the origin of life and its evolution through plants and animals. It also helps in his discussion of the development of man; and up to this point the story that Cloud tells is as fascinating as some of the best fiction and surely has something new to impart not only to the layman, for whom the book is primarily intended, but also to all but the most erudite of Earth scientists. Up to this point, too, it has a convincing air of authority about it.

Unfortunately, perhaps, Cloud's predilections and the logic of the global linkage concept then lead him on inexorably to consider the future of

Homo sapiens in the context of the impending ecological crisis which, as hundreds of books and articles have told us already, is serious precisely because of global interactions. But however sincerely meant, this is the least satisfactory part of the book, partly because it is difficult to find anything genuinely new to say and partly because Cloud ignores or underplays an essential part of the argument.

His general solution, shorn of all detail, is "strategic research and planning involving all sectors of society". He may be right; but even though he acknowledges that the growth of technology since World War II has had unforeseen side-effects that must now be mitigated, he fails to observe that mitigation through planning itself has deleterious consequences. For as experience in Britain,

the USSR and, indeed, America has plainly shown, the quality of decision-making almost invariably deteriorates when placed in the hands of an anonymous and inflated state bureaucracy (which is what always develops from 'planning'); and the institution of planning, whether effective or not, is only ever achieved at the expense of freedoms. The cure may or may not be worse than the disease, but it needs more discussion than Cloud seems to suppose.

Even so, *Cosmos, Earth, and Man* is precisely the sort of book intelligent students and laymen should be reading. If everyone agreed with everything in it, it would probably be dull. Preston Cloud is never that. □

Evocative of Dirac

R. H. Dalitz

Directions in Physics. By P. A. M. Dirac. Edited by H. Hora and J. R. Shepanski, with foreword by Sir Mark Oliphant. Pp. 95. (Wiley: New York and London, 1978.) \$16.45; £9.20.

THE editors of this book are to be congratulated on their initiative in persuading Professor Dirac, now retired from the Lucasian Chair at Cambridge and resident at Florida State University, Tallahassee, to make a lecture tour of Australia and New Zealand in 1975, and on their decision to record and publish these lectures.

The printed lectures are very evocative of Dirac. As one reads, one soon hears in one's mind the well-measured tones of Dirac's lecturing style. They capture precisely his simplicity of statement and clarity of logic. The lectures range quite widely in topic. The first lecture, "The Development of Quantum Mechanics", is primarily historical, and of particular interest concerning the precise steps of thought in the early development of non-relativistic quantum mechanics, as Dirac joined in following the initial ideas of matrix mechanics as put forward by Heisenberg.

The second lecture, on "Quantum Electrodynamics", is concerned with second quantisation, the particle representation corresponding to a wave field, and the field-theoretic formulation of the Hamiltonian for a system of charged particles. With relativistic quantum mechanics this leads Dirac to the prescriptions of renormalisation for

Dirac in 1978

dealing with the problem of divergent integrals in the perturbation calculation of quantum electrodynamic processes. Dirac is unwilling to accept the conventional renormalisation philosophy and feels that there is a change needed in the theory, "just about as drastic as the passage from the Bohr orbit theory to the quantum mechanics".

The other three lectures are more speculative. "Magnetic Monopoles" is a topic which Professor Dirac has found attractive from quite early times. Its discussion led him to his well-known result that magnetic monopoles, if they exist, should have a quantised strength, with magnitude given by the formula $n(hc/2e)$, where e denotes the unit of charge and n is an integer. In this lecture, Dirac gave attention to the question of how these magnetic monopoles might appear in experiment; and since the lecture took place soon after the publication of a cosmic ray investigation at Berkeley which claimed

to show evidence for the existence of a magnetic monopole, it was natural for him to discuss this evidence. The lecture almost coincided with the cogent criticisms made by Professor Alvarez of this interpretation of the Berkeley evidence. Dirac has, somewhat unwisely, added an appendix to this lecture, stating that the alternative interpretation by Alvarez is now disproved; in fact, Alvarez's interpretation still stands as a possibility, as does the interpretation given here by Dirac. In this situation few physicists today believe that this event gives any appreciable support for the existence of magnetic monopoles. As Dirac says, "one very much hopes that further examples will be discovered in future experiments", for that is the only way the matter can be settled.

The fourth lecture, on "A Positive-Energy Relativistic Wave Equation", is relatively technical, being concerned with a generalisation of the equation Majorana proposed in 1937 for neutral, massless fermions. This new equation finds serious difficulties when any attempt is made to extend it to the case of a charged particle; Dirac's conclusion is that the particles must be neutral or else the equation modified. The fifth and final lecture, "Cosmology and the Gravitational Constant", is based on Dirac's *Large Numbers Hypothesis*, that the very large dimensionless numbers occurring in our description of the Universe should be related with one another. Dirac focuses attention on three such numbers, (e^2/Gm_em_p) , $(m_e c^3/te^2)$ and $\sqrt{(M/m_p)}$, where G is the gravitational constant, M the mass of the Universe and t its age. Each of these numbers is at present of order 10^{39} . Dirac concludes that, in atomic units, G and M must vary with the age of the Universe, in particular that there must be a continuous creation of matter going on, a process which may be either evenly distributed over all of space or concentrated where there is already mass. The various possibilities can be distinguished by experiment, as Dirac points out, and he surveys the status of such experiments to date, leaving us with the hope that the question may become settled within a few years. This lecture is particularly interesting in the way it illustrates the simple and logical steps which Dirac's mind follows in his development of questions in physics.

These lectures have permanent value partly for historical reasons and partly because of the picture they give of the man. The lectures impinge on a number of interesting questions, for example, the relationship of Dirac's development of quantum mechanics with the ideas of Heisenberg. They give the reason (p16) for his proposal that the negative energy solution for the

Three Major New Publications For Plant Biologists

Advances in the Biochemistry and Physiology of Plant Lipids

Proceedings of the International Symposium, a "Recent Advances in the Biochemistry and Physiology of Plant Lipids", held in Göteborg, Sweden, August 28-30, 1978

edited by LARS-ÅKE APPELQVIST and CONNY LILJENBERG

DEVELOPMENTS IN PLANT BIOLOGY, Vol. 3

1979 x+456 pages Price: US \$61.00/Dfl. 125.00
ISBN 0-444-80129-4

CONTENTS: Section A: Opening Lectures. B. Membrane Lipids: Structure and Function. C. Lipid Composition and Analysis. D. Lipid Biosynthesis in Plant Cell Cultures.

Although the topic, lipids in plants has received little attention in the past, the recent realization that lipids can play a key role in the elucidation of such diverse areas as the structure and function of the photosynthetic apparatus, and the increased production of vegetable oils, led to a considerable interest in this meeting. Consequently, the book, which reviews the field from a variety of disciplinary viewpoints, will be of great value to anyone concerned in this area of rapidly growing significance.

Photosynthesis in Relation to Model Systems

edited by J. BARBER, *Imperial College of Science and Technology, Department of Botany, Prince Consort Road, London, U.K.*

TOPICS IN PHOTOSYNTHESIS, Vol. 3

1979 xii+434 pages Price: US \$87.75/Dfl. 180.00
ISBN 0-444-80066-2

The growing necessity for alternative energy sources to fossilized photosynthetic products is rapidly becoming one of the most significant problems of our time. This volume, the third in the series, Topics in Photosynthesis, highlights those aspects of the photosynthetic process which may have implications in the developments of practical

devices for solar energy, capture and storage - and thus constitutes a most important contribution to progress in solving this problem.

Over the past decade much research has been devoted to the construction of models to simulate photosynthesis, or parts of it, in an attempt to achieve one or another of the objects of the photosynthetic process itself. This book reviews practically every approach that has grown up in the last decade or so towards this end, and in so doing sheds light on the special features of the photosynthetic apparatus which would be worth consideration when trying to develop new technologies designed to help alleviate the energy supply problem.

Photobiochemistry and Photobiophysics

Managing Editor: H. METZNER
Institut für Chemische Pflanzenphysiologie
Universität Tübingen, Corrensstr. 41,
7400 Tübingen, Germany.

Aims and Scope

The journal will provide an interdisciplinary medium for the rapid publication of concise papers on all aspects of photobiochemistry and photobiophysics. Contributions in related fields such as the photochemistry of biologically relevant compounds, model reactions and data processing of

visual systems are also acceptable. Papers may include new experimental results, description of new methods or new interpretations of existing data. Purely descriptive contributions as well as the presentation of preliminary and inconclusive results are discouraged. The journal will also publish book reviews and announcements of important meetings.

1979: Volume I in 6 issues.
Subscription Price: US \$75.50/Dfl. 155.00

AND NOW THERE ARE FOUR UNIQUE FIELD GUIDES...

THE NATURAL HISTORY OF BRITAIN AND NORTHERN EUROPE provides, for the first time in a single volume, all anyone needs to know about the wildlife in a particular area. Plants, mammals, fish, insects and birds are all covered where relevant.

When the first two titles, *Towns and Gardens* and *Mountains and Moorlands* were published last year, *Homes and Gardens* called them 'elegant and practical: absolutely packed with free-from-jargon text, fine pictures and scores of magnificent drawings... the opening ecological essay by the author should be required reading in every school in the country'.

Now, two new volumes in this much-acclaimed series (General Editors: James Ferguson-Lees and Bruce Campbell) have been published – *FIELDS AND LOWLANDS* by Derrick J. Boatman and *COASTS AND ESTUARIES* by Richard S. K. Barnes. The final volume, *RIVERS, LAKES AND MARSHES* will be published next year.

THE NATURAL HISTORY OF BRITAIN AND NORTHERN EUROPE

IMMUNIZATION OF CHILDREN

INSERM Vol. 79, 440 pages / 80FF / 20 US dollars air mail postage included
46 contributions, 31 in French with summaries in English, 15 in English

Proceedings of the symposium organised in June, 1978, by the French National Institute of Health and Medical Research (INSERM), the International Children's Centre (I.C.C.) and the W.H.O.

Edited by Dr Colette FILLASTRE (I.C.C. Epidémiologic Pilot Station, France) and Dr Jeffrey EDSALL (University of California, La Jolla, U.S.A.)

This book presents current developments in vaccines, bacterial and viral (new vaccines, laboratory controls), immunization techniques, planning and fulfilment of national immunization programmes, deals with ethical and epidemiologic problems and makes suggestions on how to apply the use of basic research to public health.

5 sessions with bilingual syntheses by:

Frank Perkins (W.H.O. Geneva, Switzerland); Ph. Lagrange (Paris, France), Hanz Cohen (Bilthoven, Holland); Helio Pereira (Pirbright, Woking, G.B.), J. A. Dudgeon (London, G.B.); Colette Fillastre (Paris, France) and Michel Rey (Clermont-Ferrand, France)

electron might have been a representation of the proton. His firm belief that physics should follow "standard mathematics" is expressed very strongly in these lectures, and brings him to the point (p36) where he is willing to give up special relativity rather than accept renormalisation. One finds this a somewhat strange opinion from the man who, after all, introduced the δ -function into physics at a time when it was mathematically disreputable. The picture which he gives of the early days of quantum mechanics is most interesting, and there is one especially quotable remark, namely that "it was very easy in those

days for any second-rate physicist to do first-rate work . . . It is very difficult now for a first-rate physicist to do second-rate work". While accepting the latter proposition, we may remain somewhat sceptical about the former.

This book of lectures goes beyond history, although already interesting for that reason, and gives us also an interesting picture of Professor Dirac's ideas of recent years. Altogether, the book is very stimulating to read and deserves a place in every science library. □

R. H. Dalitz is Royal Society Research Professor in the Department of Theoretical Physics at the University of Oxford, UK.

From quarks via tokamaks, to quasars

P. T. Matthews

A Perspective of Physics. Vol. 2. Selections from 1977 Comments on Modern Physics. Introduced by Rudolf Peierls. (Gordon and Breach: London, New York and Paris, 1978.) £16.70.

UP to the outbreak of World War II the physicists who had discovered quantum mechanics and were engaged in developing its exciting implications in nuclear, atomic, molecular and solid-state physics and astrophysics, formed a close-knit international group, small enough for each individual to follow in some detail the activities of the whole. When work on basic physics started up again after the War, it was in much the same spirit; and it was not unreasonable to attempt to keep pace with the published literature as it appeared. This did not last long. The search for fundamentals led to a whole new international community of high energy, or elementary particle physicists, working in the newly discovered sub-nuclear domain, while each of the separate areas mentioned above developed into a major field of operation with its private army of specialists communicating within its own boundaries through an ever increasing flood of specialised literature.

The pace got hotter and by the mid-1950s the published literature became largely irrelevant because it took too long for an important advance to appear in print. Research groups working on related topics all over the world, but particularly in Western Europe and America, started communicating with each other by exchange of pre-prints and conference

reports. This scientific samisdat, even within a discipline such as high energy physics, tended to produce a fragmentation into subgroups very well informed within their own narrow speciality but increasingly isolated from each other. In 1967 *Comments on Nuclear and Particle Physics* was founded in a deliberate effort to counteract this trend. In the foreword to the opening volume it is explained that a group of distinguished physicists will each be asked "to comment on work that seems to him interesting and important" in the hope that new ideas would be made available "not only to specialists in the field, but also to colleagues working in related and unrelated areas of physics". Other issues in other fields followed and although the appearance of *Comments* did not change the face of physics, there is no doubt that over the years it has helped to break down the barriers of overspecialisation.

The volume under review is the second in an annual series which takes this process one stage further. It consists of a selection of reprints of some 25 articles which have appeared in

Comments on Modern Physics during 1977. The selection has been made by Sir Rudolph Peierls. The articles are split fairly evenly under the five main headings of nuclear and particle physics, solid-state, astrophysics, atomic and molecular and finally plasma physics. The selection is preceded by an introduction written by Sir Rudolph which straddles the whole field and so puts the individual articles into some coherent context. As the blurb on the dust cover rather grandly says, the whole is an attempt "to keep both the specialist reader and interested observer abreast of the most significant developments in all modern physics".

This is a very ambitious project which probably succeeds as well as could be expected, almost exclusively as a result of Peierls' masterly introduction. Without it the collected reprints would be a jumble of fragments which would add up to very little indeed. In 25 pages, which are commendably free from specialist jargon which so often obscures such articles, Peierls gives a broad brush account of the whole background which places each of the separate papers in an intelligible relation to the rest. The fact that this is done by someone already some years past official retirement, demonstrates by example that physics is still a coherent whole, and that one man prepared to make the effort can still see it as such and can follow its major developments all the way from quarks, via tokamaks, to quasars. □

Professor P. T. Matthews was Head of the Department of Physics, Blackett Laboratory, Imperial College, from 1971-76, and is now Vice-Chancellor of the University of Bath, UK.

Mechanism of organic evolution

Evolution. By C. Patterson. Pp. 197. (Routledge and Kegan Paul, in association with the British Museum (Natural History): London, 1978.) Hardback £5.95; paperback £2.95.

At the time of the Fifteenth International Congress of Zoology in 1958, the Natural History Museum in South Kensington, London, under Sir Gavin de Beer mounted a "permanent" evolution exhibit in the Main Hall of the Museum to commemorate in part the paper by Darwin and Wallace "On the Tendency of Species to form Varieties; and on the Perpetuation of Varieties

and Species by Natural Means of Selection", read at a meeting of the Linnean Society in London on 1st July 1858. To accompany the Exhibition, the Museum published *A Handbook on Evolution*, consisting of a general essay on natural selection and a guide to the exhibits. This *Handbook* was used by generations of students.

Twenty years later, the evolution exhibit has gone and the 1958 *Handbook* now seems very superficial. We are promised a new exhibit at the Museum in due course but in the meantime the Museum's Trustees (in association with Routledge and Kegan Paul) have produced a really excellent small book on *Evolution* by Colin Patterson, who works on fossil fish at the Museum. This is a completely new book which describes and summarises

the process and mechanism of organic evolution independently of any Museum exhibits. Dr Patterson is splendidly eclectic and suitably acerbic in his reviews of the concepts and controversies that contribute to our present understanding of the diversity of life.

As is proper for a taxonomist, Dr Patterson begins with a discussion of the idea of species; and as is proper for a palaeontologist, his concept of a species is three-dimensional (based on "community of descent" rather than "community of resemblance"), and includes the reality of intraspecific variation and differentiation. This leads him on to three chapters on basic genetics, and a further three on ecological and population genetics, culminating in a description of the origin of species—the subject which Darwin did not cover in his book on the *Origin of Species*; and then to a description of speciation in the Galapagos Islands. The last third of the book contains chapters on evolution beyond the species level, proof and disproof (in which Patterson largely discounts the Popperian view that evolution is metaphysics rather than science), the origin and early evolution of life, evolution and man (sadly playing down de Beer's arguments about neoteny in favour of regulatory genes, which amount to the same thing but are much more difficult to visualise), and a Who's Who of significant evolutionists (largely illustrated with portraits from the Linnean Society's collection).

The writing is concise but clear. I can think of no other book more suitable as a general introduction to the field of evolution as a whole, or for pre-university examinations in particular. There is a brief list of "further reading" which will be a useful guide to librarians.

Patterson steers a careful course through the minefield of evolutionary controversy; one of his reasons for claiming evolution is scientific is that the debates and progress pertinent to evolution have been about a series of specific questions—the relationship between ontogeny and phylogeny, the nature of particulate inheritance, the population genetics revolution in the 1930s, DNA in the 1950s and most recently the neutralist/selectionist argument. He skirts round the clade and grade dissension which is currently raising the temperature of systematists (*Nature*, 276, 759-60; 1978). Perhaps the only area in which Patterson is not entirely fair is in the relationship between evolution and Christianity; and he is hardly to be blamed because of the ability with which Christians from Soapy Sammy Wilberforce onwards have obfuscated their position.

The problem about evolution for Christians is that it seems on the surface to dispose of the need for a creator. The naive solutions are in Patterson's words:

"at one extreme the fundamentalist view that evidence of evolution, such as fossils, was built into the newly-created rocks to tempt us or test our faith. At the other extreme is the person to whom evidence of evolution only pushes the activity of the Creator further and further into the past. Both these modifications of the original creation myths are typical evasive moves, avoiding refutation or confrontation by modifying the original theory or erecting subsidiary defensive theories around it".

True, and Patterson comes close to

a positive approach to the old dispute when he points out that it is equally "depressing to be . . . a pointless experiment in protein chemistry or an experiment in ethics, which is the Christian message read from the same nihilist or 'nothing but' viewpoint".

The logical fallacy of 'nothing but-tery' has been recognised at least since the time of Aristotle; the fact that the same event may have more than one cause ought to have been assimilated by now—by both scientific reductionists and religious simplacists.

R. J. Berry

R. J. Berry is Professor of Genetics at University College, London, UK.

Appealing astronomy

Beyond the Moon? Written and presented by Simon Mitton. (ATV: London, 1979.) First programme transmitted in the UK: 09.10, 21 April, on ATV (Midlands). Other channels: morning, 22 April, 1979.

In view of its position as the most 'popular' of the physical sciences, astronomy has all too little television time allocated to it. ATV is therefore to be congratulated on running a seven-part introductory series, "both for those who are interested in the subject—and those who think they might be." In each programme Simon Mitton, as both writer and presenter, takes up a different strand and develops it from the historical point of view within a loose framework, which begins traditionally enough with the planets, and extends to encompass the stars, life in the Universe, interstellar travel, and the "far future".

The historical aspects are enlivened with biographical details which paint astronomers as real people; one appealing sequence was the summary of Newton's achievements in terms of the illustration on the current £1 notes. Despite Mitton's breathless enthusiasm, however, the production is too often constrained by a rigid studio format: presenter at desk with TV monitor. The programmes impress most through their studio demonstrations and film sequences. Demonstrations in the planetary programme range from antique orreries to a water bath for floating models of the low-density giant planets. Some of the demonstrations are unfortunately impressive at the expense of basic physics: the buoyancy of a helium balloon in air is adduced as evidence that the Earth's gravity is incapable of retaining helium atoms, and in a comparison of the weights of model gas molecules helium is represented as He₂. One surprisingly successful de-

monstration was a simple scale model of the Sun, Earth and Moon, that conveyed powerfully their relative sizes and distances, and the general emptiness of interplanetary space.

Film sequences from the Royal Greenwich Observatory and the Cambridge Institute of Astronomy provide strong links with the realities of observational astronomy. For example, the opening programme, though perhaps biased to the possibilities open to amateurs at the expense of the excitement of current research, is imaginatively set within the dome of the Isaac Newton Telescope; and in a later sequence, Mitton recounts the story of the discovery of Neptune from the dome of the Northumberland telescope, the instrument with which Challis almost forestalled Galle's identification of this new planet.

Although the series is carefully thought-out, the programmes seem to suffer from the limits on air-time and budget-restrictions: for example, the animations are crude, and some of the studio and film shots should have been retaken. Among the latter are some shots where slips of the tongue have unfortunately been allowed to survive: a light year is described as "10 million million miles" (rather than kilometres), and Jupiter's 'year' as 13 yr (instead of 11.9 yr), to take just two early examples. In addition, some viewers may find Mitton's presentation slightly patronising. To take one example, a description of 8×30 binoculars as "suitable for sport, and all right for ladies to do astronomy" will not be popular in some quarters. And a half-hour programme without interviews, and with only one presenter, can seem very long. Still, astronomy is an exciting subject, and Mitton's enthusiastic presentation is likely to convince even the casual viewer that astronomy is a subject he should learn more about.

Nigel Henbest

Nigel Henbest, formerly a researcher in radio astronomy, is now a freelance journalist.

obituary

Ralph A. Sawyer

RALPH ALANSON SAWYER, physicist and science administrator, died on 5 December 1978 at the age of 83.

Born in New Hampshire, he graduated valedictorian of his class from Dartmouth College in 1915 and then went to the University of Chicago on a travelling fellowship as a Chamberlain Fellow from Dartmouth. At Chicago he became one of R. A. Millikan's students and, after a brief tour in the US Navy, he received a PhD degree in physics there in 1919. Soon afterward Ralph joined the staff of the physics department at the University of Michigan and, except for the years of World War II, he served the University as a prolific researcher, dedicated teacher and, later, as a gifted administrator until his retirement in 1964.

Before he was called back into active service by the Navy in 1942 Ralph had published more than 50 papers in the field of spectroscopy. His interest in the spectra produced by energetic light sources, which began with his first publication at Chicago on the characteristics of a vacuum spark, continued into his earlier years at Michigan. Using a normal-incidence vacuum spectrograph of his own design, together with an improved hollow-cathode light source, for the extreme ultraviolet, Ralph and his students analysed the first spark spectrum of a considerable number of elements.

In the mid-thirties he became interested in rapid quantitative spectrochemical analysis and together with H. B. Vincent he developed the techniques to the point where a technician could make 'on line' determinations of the composition of samples in the steel-making process fast enough to control the composition of the batch of metal being processed.

From 1942 to 1945, on leave from the University, Sawyer served as Director of the Armor and Projectile Laboratory at the Naval Proving Ground at Dahlgren, Virginia. However, he still maintained an active interest in spectroscopy and managed to finish his book *Experimental Spectroscopy* which was published by Prentice-Hall in 1944 and then, in revised form, in 1951. A third, paperback, edition was published by Dover in 1963.

In 1946 Sawyer was appointed Civilian Director of Technical Operations for the series of atomic bomb tests at Bikini Atoll known as 'Opera-

tion Crossroads'. In view of the fact that he was both a Naval officer and an eminent scientist of proven administrative ability this was an ideal choice. The successful completion of this mission marked the end of Ralph's active service to the Navy and he was awarded their Commendation Ribbon. Later (1951) he was promoted from the rank of Commander to that of Captain in the Naval Reserve.

While the Bikini tests were in progress Sawyer was notified of his appointment as Dean of the Graduate School at Michigan and in the fall returned to Ann Arbor to assume the position which he held until his retirement.

Ralph's talent for administration brought him additional responsibilities. He became the first director of the Michigan Memorial Phoenix project which was devoted to the study of the peaceful uses of atomic energy and then, in 1959, he was appointed to the newly-created post of Vice-President for Research at the University of Michigan. These were times of new and rapidly expanding Federal support of university research and Ralph was in large measure responsible for establishing the University of Michigan as one of the leaders in Federally-sponsored research.

Amid all these activities Sawyer somehow found time for service to various off-campus organisations. He served a term as President of the Optical Society of America and, earlier, was an associate editor of their journal. In 1963 he was awarded the Frederic Ives medal by the Optical Society for 'distinguished work in optics'. Ralph was elected to the Governing Board of the American Institute of Physics in 1954 and served as its chairman from 1959 to 1971. This was a period in which many hard decisions had to be made and Ralph was described by one of the board members as a 'benevolent but firm leader, deeply respected by all'. Upon his retirement from the chairmanship he was awarded the Karl Taylor Compton gold medal by the Institute for 'distinguished statesmanship in science'. Sawyer also served a term as President of the Association of Graduate Schools and was advisor to or member of: the National Research Council, the Goddard Space Flight Centre, the National Bureau of Standards, the International Commission on Optics, and three US Naval Laboratories.

It can truly be said of Ralph Sawyer

that 'he lived a life of large usefulness'. Those of us who knew him well will miss his warm friendship and the entire scientific community will mourn the loss of his leadership.

W. Wallace McCormick

D. I. Blokhintsev

DMITRII IVANOVICH BLOKHINTSEV, the founder of the Soviet nuclear power industry and a prominent theoretical physicist, died suddenly on 27 January 1979. Although 71 years old, he was still actively involved in teaching at Moscow State University—his own alma mater—and in his work as head of the Laboratory of Theoretical Physics at the Joint Nuclear Research Institute at Dubna.

Blokhintsev had formerly been director of the Dubna Institute, from its foundation in 1956, until his official retirement in 1965. It was here that, in 1964, he announced the synthesis of element number 104. The Dubna institute was one of the first major joint efforts of the socialist bloc—the Comecon countries, with the addition of China, North Korea, North Vietnam, and Albania. As Director of the Institute, Blokhintsev received a number of orders and medals from the countries involved, as well as election to several foreign Academies.

Soviet honours, too, were bestowed on him, including the title of Hero of Socialist Labour, the Order of Lenin (four times), the Order of the Red Banner of Labour, the Order of the October Revolution and the Lenin and Stalin (now State) prizes. Many of these awards, including the Lenin Prize, were associated not so much with his academic talents but with his expertise as an organiser of the Soviet Union's nuclear power programme. In 1954, he was in charge of the construction of the Soviet Union's first nuclear power station, a modest 5,000 kW 'semi-pilot' plant at Obninsk, which was to do much, in the following decade, towards the development of Obninsk as a scientific centre with a wide range of research institutes.

Nevertheless, Blokhintsev's achievements in pure physics did not go unnoticed at home. Indeed, in the official *Pravda* obituary, which was signed by numerous high-ranking officials, including Messrs Brezhnev and Kosygin, pride of place is given to these. In the words of this official appreciation 'he enriched world science by his fundamental works in the field of quantum

theory, solid-state semiconductor physics, acoustics of inhomogeneous media, quantum mechanics, the theory of chain reactions in atomic reactors, and the physics of elementary particles. His death, it says, is a serious loss to Soviet science. *Vera Rich*

Peter Bishop

DR PETER MAXWELL FARROW BISHOP, FRCP (Lond.), FRCOG, one of the pioneers of British clinical endocrinology, died on 19 January 1979 at the age of 74. His main achievements were in gynaecological endocrinology, of which he was the prime mover in the United Kingdom.

He was born on 14 August 1904, the son of a doctor, and was educated in Berlin and at Charterhouse, Trinity College, Oxford and Guy's Hospital Medical School, from which he qualified in 1929.

He entered the clinical field from the physiology laboratory at Guy's Hospital Medical School, where he was demonstrator and lecturer from 1930 onwards and where his researches included the modification and application of the Friedman test for pregnancy. With the help of a physician and in liaison with the gynaecological department, he started an endocrine clinic for functional menstrual disorders in 1934. He studied the effects of oestrone in amenorrhoeic women and of the new corpus luteum extract (progestin), soon replaced by synthetic progesterone, in dysfunctional uterine bleeding and recurrent abortion. The clinic later expanded to include testicular and other endocrine disorders.

He was quick to recognise the clinical applications of recent animal experiments and was in close touch with new developments in the pharmaceutical field. Thus he applied the concept of the oestrogen threshold for uterine bleeding developed by Zuckerman in primates and, following the experiments of A. S. Parkes and his colleagues in rats, he was the first to demonstrate the effectiveness of crystalline oestrone implanted subcutaneously in a human female castrate. At the request of the Therapeutic Trials Committee of the Medical Research Council, he undertook the first clinical trial of the earliest synthetic oestrogen, diethylstilboestrol, synthesised by E. C. Dodds and his colleagues in 1938.

His researches were interrupted by the Second World War, during which he was preoccupied with administrative duties at the hospital, although he continued his clinical work and studied with S. J. Folley the rates of absorption of various hormones from subcutaneously implanted pellets.

After the war he was appointed Consultant Endocrinologist to Guy's Hospital and Chelsea Hospital for Women and Senior Lecturer in the Obstetric Department at The Royal Postgraduate Medical School. At Chelsea he made painstaking studies of the comparative potencies of various synthetic oestrogens, as determined by the dosage required to induce withdrawal bleeding in amenorrhoeic women. He also published further studies of the use of implanted progesterone in women with recurrent abortion. At the same time, with his gynaecological colleagues at Chelsea, he established a clinic for the investigation and management of infertility. He also took part in the first British clinical trials of ACTH and cortisone in rheumatoid arthritis in 1950. In later years he and his colleagues were involved in a variety of publications, including the use of dydrogesterone in dysmenorrhoea, induction of ovulation with clomiphene, the use of oral contraceptives, genetic studies in gonadal dysgenesis and the management of Cushing's syndrome.

He was a fine teacher and excelled in his lectures on various endocrine topics and clinical demonstrations of endocrine disorders. Not only undergraduate students but many young physicians and gynaecologists, both at home and from overseas, gained their knowledge and experience of endocrinology under his guidance. His writings were extensive, lucid and stylish. Apart from his original articles he wrote monographs on gynaecological endocrinology and on the chemistry of the sex hormones. He also wrote single-handed the 7th edition of *Recent Advances in Endocrinology* (1954) and contributed numerous chapters to other textbooks and invited articles to various journals for the general reader.

He was at various times President of the Section of Endocrinology of the Royal Society of Medicine and Chairman of the Society for the Study of Fertility and of the Council of Management of the *Journal of Reproduction and Fertility*. He was also Medical Consultant to the Family Planning Association.

Dr Bishop had the unusual distinction of being elected Fellow of both The Royal College of Physicians and The Royal College of Obstetricians and Gynaecologists. He was Sir Arthur Sims' Travelling Professor in 1964. In the year of his retirement from hospital in 1969 he became Master of the Society of Apothecaries.

He retained single-minded dedication to clinical endocrinology throughout his career despite considerable scepticism and opposition from others. This required great determination and

courage: qualities which he likewise displayed in the face of the physical disability which followed his retirement and immobilised him for the last few years of his life, but which never extinguished his interest in his subject nor his zest for living.

Robert R. de Mowbray

Fred Lang

THE death of Dr Fred Lang at the age of 34 in an automobile accident on 8 December 1978, cut short a promising career in neurobiology. He was Associate Professor of Biology in Boston University; he taught in the Boston University Marine Program at Woods Hole, Mass., and was a director of the winter neurobiology course given there. Recently he had received a Career Development Award from NIH to further his research on invertebrate neuromuscular systems, which had reached a flourishing stage and had attracted a large entourage of graduate students at Woods Hole.

Fred Lang worked as a graduate student with Bernard Abbott and Ladd Prosser at the University of Illinois, and as a postdoctoral fellow with Harold Atwood at the University of Toronto. His initial work on the innervation of the heart of the horseshoe crab *Limulus*, and on neuromuscular physiology of crustacean limbs, was extended later to include development of neuromuscular synapses in crustaceans, and in particular, development of the nervous system and muscles in the American lobster, *Homarus*. He and his collaborators described the physiological properties of the differentiated asymmetric 'crusher' and 'cutter' claws of the lobster, and then looked for neural and environmental influences on differentiation. In addition, adaptation of the animal to its environment was examined. A thorough description of physiological and morphological changes occurring in the muscle fibres throughout development led to a correlation of muscle fibre properties with their innervation and to a demonstration that muscle differentiation could be influenced by conditions in the animal's environment. Although this evidence suggests a neural influence on muscle differentiation, the problem remains open and controversial.

His enthusiastic activity, his lively and forthright dialogue, and his ability to generate interest and debate, will be well remembered. He had an important place among invertebrate neurobiologists.

Simultaneous TG-DSC vs. Guesswork

Thermogravimetry (TG) and heat flow Differential Scanning Calorimetry (DSC) are two important thermoanalytical measuring methods which complement each other in a virtually ideal manner.

The new TA2000C Thermoanalyzer from Mettler supplies simultaneous TG and DSC data in the $+20^{\circ}\text{C}$ to $+1200^{\circ}\text{C}$ temperature range from a single sample. This provides objective information about decomposition reactions, phase transitions, enthalpy and weight changes. All of which can be used to draw objective conclusions about the temperature behavior of substances.

The operation of the TA2000C, however, is very simple. Its freely accessible furnace, the problem-free automatic push-button design of its balance, and the easy operation of its vacuum and temperature programs reduce training time, yet raise the quality of the analyses. As a result, operating errors are almost completely eliminated.

Objectively speaking, these are all very good reasons for using simultaneous TG-DSC. From now on, there is no longer any need for making guesses about the temperature behavior of substances.

what's new

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover.

A feature on spectrophotometers will appear in the 17 May issue.

Temtron

THE Temtron Micro Stirrer is designed to continuously stir micro quantities of aqueous chemical compounds. Previously this has not been possible under certain restrictive operating conditions. But a method is now available to enable scientists to not only stir effectively, but to add further preparations to existing compounds without ever handling the cuvette or disturbing the sensitive, fully enclosed detector system of the analyser. The stirring rate is continuously variable over 0–30 Hz. An 11×11×5 mm energiser capsule is placed under the cuvette and drives a Teflon coated stir bar magnet. By means of a special Temtron development, cuvettes (e.g. 1 ml) having internal physical shape restrictions as small as a 3×10 mm opening, which would normally be impossible to stir, can be accommodated. The Micro Stirrer does not interfere with light sensing detectors.

Circle No. 77 on Reader Enquiry Card.

The Temtron Microstirrer

Canning

DETERGENT N22646 is a non-alkaline surfactant which can be used at a concentration of $\frac{1}{2}$ to 1½% in water for the removal of oils and greases. At different concentrations it can also be used for special applications as a scratch brushing fluid; for washing out polished silverware; for barrel finishing; for cleaning prior to plating on plastics and in hot water rinses.

The Model 2616 infusion pump from Harvard

Harvard Apparatus

A low cost infusion pump for critical drug infusion applications has been introduced by Harvard Apparatus. Model 2616 has a reliable solid-state design, allowing a digital infusion rate of anything from 1.0 ml per h to 9.9 ml per h in 0.1 ml per h increments. Its syringe drive, powered by a rugged motor driving a precision lead screw assures dependable operation over prolonged periods of daily usage.

Harvard also offer a wide range of multi-speed pumps for infusion and withdrawal of liquids. These pumps are very accurate and offer a wide choice of flow rates by using different sized syringes (anything from 2 to 200 ml) together with the ability to change the motor speed. Output pressures of over 150 p.s.i. are possible in all pump series. The different model series include single action infusion or withdrawal, reciprocal action, and continuous-automatic operation with solenoid-operated tubing output. Many series offer multiple channel pumping.

Circle No. 79 on Reader Enquiry Card.

LTE

A COMPLETELY new range of ovens and dry heat sterilisers has been designed by LTE conforming to the latest thinking in hot air sterilisation. The Series G models have a modular control panel for maximum flexibility when choosing control options; a solid state controller for accuracy and ease of service; a stainless steel working chamber, and a performance better than the B.S. 2638 and B.S. 3421 requirements for ovens. Both the ovens and sterilisers come in three different sizes ranging from a capacity of 80 to 215 litres.

Circle No. 80 on Reader Enquiry Card.

Prot

VIAL washers, liquid fillers and cappers are now available from Prot. Vial washers come with four different types of working cycles and in various sizes to accommodate from 3,600 to 40,000 pieces per hour. Both conventional and ultrasonic techniques are utilised and cycles may be modified to suit customer requirements. Unloading is automatic and some versions incorporate special regulation of the washing fluid. All machines are built to the highest standards with extensive use of stainless steel. Rotary bottle washers with a capacity of up to 2,160 pieces per hour are available. The range also covers bottle cappers, which have changeable heads to allow handling of closures of differing diameters. Bottle fillers are offered too.

Circle No. 81 on Reader Enquiry Card.

An oven from Electrolux of Sweden

Electrolux

OVENS and incubators from Swedish Electrolux are now available. The smallest model in the range has a capacity of 55 litres and its interior can be either aluminium or stainless steel. The former has a temperature range of 50 to 200 °C and the latter 80 to 300 °C. Both are gravity convected and have temperature variation values (throughout the cabinet) of under ±1.5 °C. Other models include larger sizes of ovens, sterilisers and incubators.

Circle No. 82 on Reader Enquiry Card.

The 17 May issue of *Nature* will feature colorimeters, spectrophotometers, fluorimeters and related equipment. Manufacturers should send information to the *Nature* office in London before 8 May.

Fedegari Autoclavi Spa

AN extensive range of high quality sterilisation autoclaves is now available and includes both steam and ethylene-oxide models. Strict quality control including exhaustive construction and weld testing ensures that these autoclaves are of the highest standards. Vertical cylinder, semi-automatic models for laboratory use have chamber capacities from 14 to 140 litres. Double wall, horizontal autoclaves can be supplied for pharmaceutical and hospital applications. These autoclaves together with the ethylene-oxide models are all available in six standard chamber sizes ranging from 70 to 1,750 litres capacity. A special super-heated water circulation unit is designed for sterilising plastic or glass vessels containing pharmaceutical solutions for which traditional steam methods are unsuitable. This model is offered in three chamber sizes of capacities from 600 to 11,000 litres. Custom-built autoclaves of any capacity can be supplied.

Circle No. 83 on Reader Enquiry Card.

Astell Hearson Swiftlock autoclave

Astell Hearson

RELIABLE dry heat sterilisation is provided by Astell Hearson's range of fully automatic sterilising ovens. The ovens are designed to give reliable sterilisation at the touch of a button. If a fault should occur such as mains failure, the cycle is automatically terminated thus avoiding the possibility of an incomplete process. The oven features push-button controls, automatic resetting cycle timer, door lock, and electronic strip-chart recorder. Once the door has been shut and the green start button depressed, the oven will heat up to the preset temperature and hold it there for the duration of the cycle. When the cycle is complete,

the heat is cut off but the fan continues to run. The door remains locked until the cooling period is complete.

A range of simple to operate laboratory autoclaves meeting all current safety requirements in full is also available from Astell Hearson. Swiftlock 2000 autoclaves are available with a thermal lock with key switch override for the processing of liquids in sealable glass containers. The Swiftlock closure is fundamentally safe and is simple to operate. The lid is easily swung into position, and the outer ring rotated through only 4 inches to close the autoclave. The processing cycle is then started by turning the control knob. This locks the lid, activates the controls and closes off a large bore vent valve. Reversal of this procedure opens the vent valve to safely release any residual steam pressure, and after a short delay, the lock is withdrawn allowing completely safe opening. The Swiftlock 2000 is available for both horizontal or vertical loading, electrically heated or direct steam heated. Sizes range from 460 mm diameter, 610 mm deep, up to 610 mm diameter, 910 mm deep.

Circle No. 84 on Reader Enquiry Card.

Chandos Intercontinental

A NEW addition to the Chandos range of stirrers is a variation of the Multi Place Unit where a master control unit operates several slave magnetic stirrers on flying leads. These stirrers are operated on low voltage from the master unit and can be placed in hazardous areas for remote operation. Applications also include fume cupboards, glove boxes etc. Most models have, as an alternative to standard motors, a variation using a 'stepping' motor triggered by a pulse generator. In multi station applications these models give identical speeds on all stations, which neither speed or slow with ambient temperature or viscosity change. Several types of pump are offered from high output low voltage d.c. submersible units to multi channel accurate dispensing peristaltic pumps.

Circle No. 85 on Reader Enquiry Card.

Chandos Multi Place Unit showing five slave stirrers operated from the master control unit

Variable-speed peristaltic pump from CP Instruments. Circle No. 76 for more details on the CP range of pumps

Chemlab

A WIDE range of PTFE covered stirring paddles is available from Chemlab. The magnets used in their construction have exceptionally high field strength to ensure excellent stirring even in viscous liquids. All paddles are moulded in one-piece and have a smooth machine finished surface to facilitate cleaning. ChemLab Retriever Rods are available for the recovery of paddles once stirring has been completed. Both the paddles and the rods and their integral magnet are PTFE covered, and may be used at temperatures up to 240 °C in all chemical reagents.

The ChemLab Model SS3H is a variable speed, hotplate magnetic stirrer for a wide variety of chemical and biochemical work. The temperature of the hotplate is controlled by a Simmerstat which regulates it between 50° and 325 °C. A heat baffle plate is fitted between the hotplate and the stirrer to prevent overheating of the internal components. Additional internal cooling is provided by a fan fitted to the stirrer motor. The ChemLab Model SS3 magnetic stirrer with its large, flat, easy-to-clean stainless steel top, powerful magnet and variable operating speed is ideal for large volumes of corrosive liquids that have to be stirred and for when very slow stirring speeds are required. An internal fan ensures efficient cooling of the drive motor.

The ChemLab Mini Stirrer is a compact, inexpensive but reliable magnetic stirrer with variable speed control. It is fitted with an exceptionally powerful magnet enabling it to stir volumes up to 5 litres when suitably supported. The white plastic case is tough, durable, easy to clean and resistant to most chemical reagents.

Circle No. 86 on Reader Enquiry Card.

Alconox

THE Alconox range of detergents includes Alconox powder a general purpose cleaner; Liqui-Nox a phosphate free liquid cleaner; Terg-a-Zyme with protease enzymes; Alcojet specially formulated for washing machines and Alcotabs for pipette rinsers and washers.

Exclusive

A hot new tracer for Vitamin D₃ studies

24,25-Dihydroxy[23,24(n)-³H]cholecalciferol TRK.616 50-80 Ci/mmol
(Current batch 80 Ci/mmol)

An important addition to the best range of Vitamin D₃ tracers available:

1α,25-Dihydroxy[23,24(n)- ³ H]cholecalciferol	TRK.588	70-110 Ci/mmol
25-Hydroxy[23,24(n)- ³ H]cholecalciferol	TRK.558	70-110 Ci/mmol
25-Hydroxy[26(27)-methyl- ³ H]cholecalciferol	TRK.396	5-15 Ci/mmol
[1α,2α(n)- ³ H]Vitamin D ₃	TRK.346	5-15 Ci/mmol

Also available

[4-¹⁴C]Vitamin D₃ CFA.455 25-35 mCi/mmol

Model AA Dohm syphon
1½ gallon per min flow rate

Dohm London

THE simple-to-use Dohm syphon safely and quickly transfers dangerous, corrosive liquids from one vessel to another, without waste, mess or personal hazard often associated with tipping and pouring from one heavy vessel to another. Manufactured from corrosion resistant polyethylene, the Dohm syphon consists simply of a tube with a tap at one end and a concertina-like bellows pump towards the other. In use, the tap is turned to the closed position, the bellows pump is compressed and the open tube end inserted in the vessel from which the liquid is to be taken. When the bellows pump is released the liquid is syphoned into the tube. By opening the tap, the liquid is allowed to flow freely into the container being filled, with the flow always readily under control at the tap. Dohm syphons are made in two sizes—1½ and 3 gal per min flow rate.

Circle No. 88 on Reader Enquiry Card.

Brentchem

THE Brentchem range of 14 specifically developed detergents, sanitisers and ancillary products for use in laboratories has been recently improved. The range includes three liquid and six powder detergents for machine washing of laboratory glassware and other utensils. Hydrosol is especially useful for washing aluminium utensils; Stretonite is a very low foam detergent for animal cages; and Lab-brite is particularly successful on tissue culture containers and similar items. There is a liquid and a powder grade for the manual washing of labware. Task and Septonite are general purpose detergent/sanitisers respectively in a liquid and a powder form, and Sorbitex is an absorbent granular clay for animal bedding and liquid spillage.

Circle No. 89 on Reader Enquiry Card.

L.I.P.

LIPOL liquid is a popular cleaner for laboratory glassware and plastics. It is an extremely active, non-toxic, non-corrosive, phosphate-free, biodegradable surfactant which is safe in use, fully compatible with hypochlorites, inexpensive and free rinsing in cold water to leave a brilliant, grease-free, clean surface. Lipol liquid completely removes biological residues and is an effective radioactive decontaminant.

A recent addition to L.I.P.'s range of small laboratory instruments is a family of magnetic stirrers and hotplates. These range from a fixed speed magnetic stirrer through a variable speed stirrer to a highly efficient hotplate and stirrer. The hotplate is also available unstirred. The fixed speed stirrer is a compact unit stirring at approximately 500 r.p.m. A 25 mm PTFE coated magnetic follower is supplied as standard. The variable speed stirrer has a continuously variable control up to a maximum of 1,300 r.p.m. The silent, long life motor is fitted with a powerful drive magnet and one of each 20 mm and 40 mm PTFE coated followers are supplied as standard. The variable speed stirrer is available fitted with a 13 cm diameter cast aluminium hotplate with a logarithmic energy regulator temperature control up to a maximum of 4000 °C. The hotplate is also available as a separate unit with no stirring facility. 20 mm and 40 mm PTFE coated followers are standard. All the units are made from robust metal and each is fitted with a mains indicator lamp. The smooth white finish provides an easy wipe clean surface.

Circle No. 90 on Reader Enquiry Card.

Nusonics

ULTRASONIC cleaning is a necessity in fields where contamination is a danger. Nusonics cleaners are powerful, robust and multipurpose, ranging from light bench models to large free-standing tanks with separate generators, one generator being sufficient to operate as many as three separate and variable tanks. Rapidex is a specially formulated biological surface-active detergent for the cleaning of laboratory and surgical equipment from all pollutants including radioactive contaminants. It is supplied for ease of use in pre-measured sachets ready for mixing with ordinary water in the ultrasonic tank, and two minutes cleaning with this solution followed by a thorough rinsing in fresh water will prepare even the most intricate article for laboratory or other use. Nusonics have formulated liquid detergents and de-greasers for any individual cleaning requirement and will always advise and work with a customer on specific cleaning problems.

Circle No. 91 on Reader Enquiry Card.

Baird and Tatlock

A NEW range of three magnetic stirrers has been produced by B & T. Using standardised casings and components, matched units designed to cope with every laboratory stirring requirement are offered. The simple laboratory stirrer (Cat. no. 333/0024) has a wrap-over top to provide spillage protection to control area and interior. It also dissipates any local heating from the stirring area. 3.2-mm thick aluminium gives a powerful eddy current effect in conjunction with the high flux stirrer magnet and allows speeds to be reliably and continuously controlled between 100 and 2,400 r.p.m. Modification of this design gives the new B & T hotplate magnetic stirrer (Cat. no. 333/0019). This allows a continuous variation of temperature up to 250 °C (230 V). A rectangular hotplate without magnetic stirrer is also available (Cat. no. 312/0066). B & T have also produced a reversible magnetic stirrer (Cat. no. 333/0026). The stirrer can be reversed in one direction only at speeds up to 2,200 r.p.m. or can reverse in an opposite direction on a 7½ second cycling function.

Series 225 autoclave (vertical model)
available from Baird and Tatlock

B & T are introducing a new series 225 autoclave. This is available for either direct steam or electrical operation using an integral generator. Control of the operating conditions within the chamber is by steam pressure. The basic unit can cope with all laboratory sterilisation requirements with optional 'plug-in' modules to record temperature, indicate temperature and to control/indicate temperature. The autoclaves are available either as a horizontal or vertical model.

Circle No. 92 on Reader Enquiry Card.

Fluid Equipment (Adelphi)

THREE variable speed laboratory stirrers are marketed by Fluid Equipment. The smallest mixes volumes of aqueous solution up to 1 litre and the largest mixes up to 100 litres. The largest, Model SL4, is a heavy duty laboratory stirrer and can be either stand or clamp mounted. It reaches speeds of up to 3,000 r.p.m. and its thyristor speed control gives greater power at low speeds.

Circle No. 93 on Reader Enquiry Card.

Adelphi SL4 stirrer

Flow Laboratories

DEVELOPED for use in tissue culture laboratories, 7X is an ideal detergent for glassware and instruments in all laboratories. As 7X is a solution it is simple to prepare the working concentration and there are no problems with undissolved particles. 7X cleans efficiently, gently and without etching and can be efficiently rinsed to give residue-free labware. For use in automatic washers Flow produce 7X O-matic.

Flow now offer three models of the Titertek plate shaker, designed to provide quick and effective re-suspension of cultures, RBCs, etc. Each shaker holds two microtitration plates via a central stud and two springs.

Circle No. 94 on Reader Enquiry Card.

Pool Bioanalysis Italiana

THE Agarster is a bench top agar steriliser unit specifically designed for the preparation and sterilisation of media under closely controlled conditions of time and temperature. Volumes of two to eight litres can be sterilised and cooled to a preset temperature in one hour or less depending upon the sterilisation time. Repeat batches take a shorter time since the unit retains some heat from the previous batch. Sterilisation temperature, sterilisation time and dispensing temperature are each preset at the start of the cycle. A water softening unit is incorporated within the unit to decrease 'furring' of the element and water jacket. Descaling can be carried out if necessary as the outer jacket is fully accessible and replacement of the element can quickly

be carried out. After sterilisation cooling water circulates in the outer jacket to cool the medium to the predetermined temperature. This temperature is maintained by alternately heating and cooling the outer jacket. Emptying of the vessel is achieved by connection of a stainless steel tube through a port on the lid and through a peristaltic pump like that used on the ADD plate pouring unit.

Circle No. 95 on Reader Enquiry Card.

Uniscience

THE new Uniscience Aquavac is a portable water jet vacuum unit which is designed to replace the laboratory tap operated water jet pumps, well known for their high water consumption and poor performance in areas of low water pressure. The Aquavac generates a constant high water pressure, independent of the water mains pressure, thereby giving constant and improved vacuums. The high air displacement up to 80 litres per min at 760 mm. Hg compared to tap operated water jet pumps (1.5 to 5.0 litres per min) provides rapid evacuation even for large volumes up to 50 litres. Recirculation of water provides a considerable saving of water. Only a small flow of water is required to the Aquavac to maintain the continuous removal of condensed products. The unit can safely handle the extraction of acid fumes and solvent vapours without the use of filters or freezing traps. It is available with 2 or 4 vacuum outlets and is ideal for laboratory and industrial scale processes including vacuum filtration and distillation, rotary evaporation, evacuation of drying ovens and dessicators, etc.

Circle No. 96 on Reader Enquiry Card.

B. Braun Melsungen

THE Potter-S tissue homogeniser ensures excellent reproducibility of results by the use of an electronically controlled drive unit operating between 150 and 1,500 r.p.m. and simple manual control of the plunger stroke length and frequency. Vessels with capacities from 2 to 60 ml are automatically aligned in a cooling jacket which has the important advantage of ensuring that there is no risk of breakage. Cell-free extracts from single-cell suspensions such as yeasts, bacteria and algae are obtained with the MSK cell disintegrator. The cells are mixed with glass micro-beads and oscillated at high speed while being cooled with liquid CO₂. High fragmentation yields of up to 99% are obtained with short homogenisation times. A high-output ultrasonic disintegrator, the Labsonic 1510, permits reproducible disintegration of all cell material such as mitochondria, chloroplasts and cell nuclei. A wide range of probes and cooling jackets

enable the Labsonic to be used for a wide variety of applications. Homogenisation of very tough materials such as connective tissue, cartilage, cancerous tissue, bone and dental enamel can be carried out using the Braun Microdismembrator.

Circle No. 97 on Reader Enquiry Card.

Braun Labsonic 1510 ultrasonic disintegrator

Newamatic

THE latest model F 570 Newamatic laboratory glassware and instrument washer is a compact bench top or plinth mounting machine offering all the facilities required in the busy modern laboratory. This sturdy machine is simple to load and operate. Apparatus to be washed is accommodated in baskets. 'Open' glassware and instruments may be loaded in simple baskets while narrower neck vessels, flasks, bottles, etc. are supported upright on racks with spigots. An exceptionally reliable pump and a patented spray and turntable system—the Jet system—ensures that water is projected on to surfaces to be cleaned with high velocity. This action, combined with fresh (not recycled) water rinses, adjustable wash temperature, the provision of up to two distilled water rinses and a built-in drier provides efficient cleaning at a competitive price.

Circle No. 98 on Reader Enquiry Card.

Italgas

A GLASSWARE washing machine specifically designed and constructed for the laboratory has been produced by Italgas. It efficiently washes all types of laboratory glassware, and although automatic it allows the operator to monitor and regulate all parameters in the easily operated, versatile washing procedure. Six interchangeable baskets cope with all types of glassware, and the push button control system allows unlimited programming.

APPOINTMENTS VACANT

UNIVERSITY OF THE WEST INDIES —BARBADOS

Applications are invited for the post of

SENIOR LECTURER/LECTURER IN THE DEPARTMENT OF BIOLOGY

Preference may be given to a person with experience and interest in animal and/or plant physiology. The appointee will be expected to assume duties by August 1, 1979, and not later than October 1, 1979. Salary Scales: Senior Lecturer BDS\$25,827 to BDS\$34,017 per annum. Lecturer BDS\$19,071 to BDS\$29,799 per annum (£1 sterling equals BDS\$4.107). F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10 per cent of salary. A housing allowance of 20 per cent of salary is payable to staff who make their own housing arrangements. Family passages. Study and Travel Grant. Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status and the names and addresses of three referees should be sent as soon as possible to the Secretary, University of the West Indies, Cave Hill, P.O. Box 64, Bridgetown, Barbados. Applicants resident in UK should also send one copy to Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further particulars are obtainable from either address 478(A).

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

CANADA
DEPARTMENT OF BIOLOGY

INSECT ULTRASTRUCTURE BACTERIAL TAXONOMY/ ECOLOGY

Postdoctoral position available September 1, 1979. The position is initially for one year to study the structure of the peritrophic membrane and gut wall of selected forest pests and renewable for a second year. The second year will involve a taxonomic and spatial analysis of the insect gut bacterial flora. Initial salary \$12,900. Send curriculum vitae and names of three referees to Dr R. A. Nolan, Department of Biology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X9 490(A).

UNIVERSITY OF LONDON KING'S COLLEGE RESEARCH TECHNICIAN GRADE 5

Required to work with Solid State Physics Group. Main responsibilities will be the maintenance, development and setting up of research equipment and preparation of samples. Experience in electronic desirable. Salary on scale £3,989 rising to £4,580 per annum. Inclusive Five weeks annual holiday. Contributory pension scheme. Interest free advance for annual season ticket. Apply in writing with full details to The Head Clerk (Ref 214729/N), King's College London, Strand WC2R 2LS. 492(A).

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS AL5 2JQ PLANT PHYSIOLOGIST

to work in the Soils and Plant Nutrition Department on investigations into the distribution and properties of crop roots in relation to their absorption of nutrients and water, as part of a group working on root-soil relationships.

Qualifications. First or upper second class honours degree in botany or biology, with good background in chemistry, and at least two years' relevant post qualifying experience. Preference will be given to candidates with a doctorate or other post graduate experience in the field of plant physiology or ecology.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,488) or Senior Scientific Officer (£5,154 to £6,898). At least four years' post-graduate research or other approved experience is required for appointment as S.S.O. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref 388 by May 18, 1979. Further details on request 457(A).

UNIVERSITY COLLEGE LONDON LECTURER IN PHYSIOLOGY

Applications are invited for a Lectureship in Physiology. Candidates will generally be expected to have a Ph.D. degree or/and a medical, veterinary or dental qualification. They should have at least three years' postdoctoral experience in research and preferably should have experience of working outside the U.K. Salary will be in the range £3,909 to £7,754 (under review) plus £502 London Allowance. Applications should include the names of three referees and should be submitted to the Assistant Secretary (Personnel), University College London, Gower Street, London WC1E 6BT by May 10, 1979, from whom further particulars may be obtained. 447(A).

UNIVERSITY OF LIVERPOOL DEPARTMENT OF MARINE BIOLOGY Port Erin, Isle of Man LECTURESHP IN MARINE BIOLOGY

Applications are invited for the above post tenable at the University's Marine Biological Station, Port Erin, Isle of Man. Applicants should have postgraduate experience in experimental marine biology, preferably in biochemical aspects of the physiology of marine animals, and will be expected to extend departmental teaching of courses in the physiology of marine invertebrates and fish.

The post is tenable from October 1, 1979 at an initial salary within the range £3,883 to £4,882 per annum on a scale rising to £7,754 per annum.

Applications, together with the names of three referees, should be received not later than May 18, 1979, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref RV/563/N 465(A).

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF CHEMICAL ENGINEERING LECTURESHP

A lecturer in Chemical Engineering is required, preferably with expertise in Biological Chemical Engineering. Some experience of Chemical Engineering drawing would be an advantage, but is not essential. The appointment will be from October 1, 1979 (or earlier by arrangement).

Salary will be on the scale £3,883 to £7,754 (under review), plus superannuation. Maximum starting salary will depend on age, experience and qualifications.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) containing a full curriculum vitae and naming three referees should be sent by Monday, May 7, 1979.

Please quote ref. NT7 444(A)

Houghton Poultry Research Station LIAISON OFFICER

Applications are invited for the post of Liaison Officer, the duties of which include liaison with, and an information service for, the poultry industry, veterinary profession, Agricultural Research Council and Ministry, the Press, journals, educational organisations, and the preparation of publications and exhibits.

Applicants should possess a degree H.N.C. or equivalent in a science subject, with at least five years' relevant experience. Experience in public relations and editorial work would be an advantage.

Salary in Higher Scientific Officer grade (£4,101 by 8 to £5,448).

Further particulars from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon Cambs. PE17 2DA. Closing date for applications: May 11, 1979 446(A).

Wyeth Institute of Medical Research

Gastroenterology

We are seeking to appoint a graduate physiologist or pharmacologist with two or more years experience of research on drugs which affect gastric secretion.

This post could be suitable for someone completing a second degree. The successful applicant will join an existing team which is committed to the discovery and development of new treatments for peptic ulcers. We are looking for someone who will be able to make an immediate contribution to the work of the section.

Please apply to:

Mrs. J. Andrews, Personnel Officer,
Wyeth Laboratories,
Huntercombe Lane South, Taplow,
Maldenhead, Berks. Tel. Slough 28311.

Wyeth Laboratories

Chemical Mutagenesis

Shell Toxicology Laboratory (Tunstall)

The Cytogenetics and Mutagenesis section of the Pathology Division at our Sittingbourne Research Centre has a vacancy for someone experienced in mammalian cytogenetics. You will be studying the cytogenetic effects of agricultural and industrial chemicals including chromosome studies on mammals, cell cultures and human lymphocytes. Your work will be divided between conventional metaphase analysis and the development of new techniques for studying the effects of chemicals on meiotic and mitotic chromosomes. Emphasis is placed on the application of automated methods of chromosome analysis using an image analyser for metaphase finding.

You should have at least a good honours degree in a subject involving genetics, a knowledge of mammalian cytogenetics and about three years post graduate experience. Preference will be given to those possessing a Ph.D. in an area oriented towards mammalian cytogenetics, or who have experience of automated cytogenetic procedures.

We offer a competitive salary and assistance will be given with relocation expenses where appropriate. You will be able to join our pension fund, enjoy flexible working hours and work in well-equipped laboratories which are situated on a 450 acre farmland site. There are also excellent facilities for sport and social activities. Please write, giving all relevant details about yourself and your career, or telephone for an application form to.

Shell Research Limited, Recruitment Division, (N1) PNE/11, Shell Centre, London SE1 7NA. Telephone. 01-934 2948.

476(A)

Pharmacologist

Miles Laboratories Ltd. are an international pharmaceutical company based in an attractive part of South Buckinghamshire.

We are currently seeking a Pharmacologist to join a team working on the therapeutic role of prostaglandins in the respiratory tract. The person would be directly concerned with studies on the classification/nature of receptors associated with the varied actions of prostaglandins in the respiratory tract and other systems. Ideally we are seeking someone with a Ph.D. or alternatively, an Honours Graduate with post-graduate research experience in pharmacology.

In return we offer excellent conditions of employment, four weeks holidays, subsidised staff restaurant, free life and private health insurance, contributory pension scheme, flexible working hours.

For an application form please write or ring my secretary on Farnham Common 2151

Mrs. Nancy Morgans
Personnel Manager
Miles Laboratories Limited
Stoke Court, Stoke Poges
SLOUGH.

467(A)

UNIVERSITY OF GLASGOW DEPARTMENT OF ELECTRONICS AND ELECTRICAL ENGINEERING

THREE RESEARCH APPOINTMENTS

Acousto-optical Devices

Three posts, financed by a Ministry of Defence Research Contract for three years, are available immediately for research on an integrated acousto-optical device for microwave spectrum analysis.

The posts are

(A) One senior engineer or physicist with an optical physics, electronics or systems research background. Starting salary up to £6,793 on Range II of the salary scales for Research and Analogous Staff.

(B) One senior Research Technologist with a background in optical fabrication techniques such as polishing and grinding. Starting salary up to £6,793 on Range II of the salary scales for Research and Analogous Staff.

(C) A graduate assistant (possibly a recent graduate), with some background in optics or optical electronics. Starting salary up to £4,631 on Range IA of the salary scales for Research and Analogous Staff.

The above posts are superannuated

For further particulars, write to Professor John Lamb, Department of Electronics and Electrical Engineering, The University, Glasgow G12 8QQ, to whom applications (two copies) should be addressed, giving the names and addresses of at least TWO referees. State for which post the application is made. Closing date May 12, 1979.

In reply please quote Ref No 4431M

499(A)

UNIVERSITY OF MALAWI CHANCELLOR COLLEGE

Applications are invited for the post of

PROFESSOR OF MATHEMATICS

Applicants should have a good first degree and a higher degree plus considerable experience in university teaching and research with some administrative research. In addition to being Head of Department, the appointee will be expected to teach third and fourth year courses in his/her specialism. At present, third and fourth year courses are offered in algebraic structures, analysis, differential equations, linear algebra, number theory, numerical methods and statistics.

Salary scale: K7,900 to K10,300 per annum (£1 sterling equals K1.65) plus either a University addition of between K1,820 and K1,920 (taxable in Malawi) or the British Government may supplement salary by £5,310 per annum (sterling) for married appointee or £4,134 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages, superannuation scheme transferable with FSSU: Gratuity 15%-25%, biennial overseas leave, housing, various allowances.

Detailed applications (two copies) with curriculum vitae and naming three referees should be sent by air-mail to Registrar, University of Malawi, P.O. Box 278, Zomba, Malawi, by June 9, 1979. Applicants resident in UK should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

479(A)

Biochemical Technician

Shell Research Limited is looking for a technician to join the Biochemical Pathology section of its Toxicology Laboratory at Sittingbourne in Kent. The purpose of the work is to assist with investigations into the effects of foreign compounds in animal tissues. You will be involved in dissecting, working with the subcellular fractionation of animal tissues, and enzyme activity measurements.

You should possess an HNC/D in Applied Biology and some experience in the above areas including the use of spectrophotometric, radiochemical and chromatographic techniques.

We offer a competitive salary and assistance will be given with relocation expenses where appropriate. You will be able to join our pension scheme, enjoy flexible working hours and make use of the excellent sports and social facilities. Please write giving all the relevant details about yourself and your career, or telephone for an application form to:

Mrs I Broodbank, Personnel Division, (N1), Shell Research Limited, Sittingbourne Research Centre, Sittingbourne, Kent ME9 8AG. Telephone: Sittingbourne 24444 ext. 203.

435(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following position

The John Curtin School of Medical Research

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOW

A position is available to work on the molecular biology of influenza viruses. In particular studies on the structural differences between variants selected with monoclonal anti-bodies. The major interests are (1) nucleic acid sequencing, using recombinant DNA technology, (2) immunochemical characterisation of the antigenic determinants of the haemagglutinin.

The appointment, which is funded by a grant from the National Institutes of Health, USA, is for one year in the first instance with probable extensions for a further two years. It is hoped that the successful applicant would be able to take up the appointment in the near future.

Salary: Commencing salary will be in accordance with qualifications within the range \$A15,786 to \$A17,716. Current exchange rates are \$A1 56p \$US1 13.

Other Conditions: A limited grant towards travel and removal expenses may be made. Assistance with housing is provided for an appointee from outside Canberra.

Applications should be sent to the Registrar, Australian National University P.O. Box 4, Canberra ACT 2600, Australia as soon as possible.

496(A)

UNIVERSITY OF BRISTOL POSTDOCTORAL RESEARCH ASSISTANT

Required from October 1, 1979 for a period of three years to join a group working on the pathogenesis of herpes virus infections. The project will be funded by the MRC and will be concerned with the interaction of herpes simplex virus with cells in culture at different stages of growth and differentiation. Experience of virology is desirable but applicants with a background of cell biology, biochemistry or pathology may be suitable. Starting salary up to £4,382 per annum (scale under review).

Further information from Dr T J Hill, Department of Bacteriology, Medical School, University Walk, Bristol BS8 1TD to whom applications, including a curriculum vitae and names of two referees 484(A)

UNIVERSITY OF GLASGOW DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistantship, supported by the Science Research Council, to undertake research into the use of chiral lithium dialkylamides in organic synthesis. The post is tenable for one year from October, 1979. Salary will be within Range 1A of the salary scales for Research and Analogous Staff (£3,975 to £4,505), according to age and experience, with USS.

Applications enclosing a curriculum vitae and the names of two referees should be sent to Dr E W Colvin, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref No 4428M.

486(A)

UNIVERSITY OF OXFORD MICROBIOLOGY UNIT DEPARTMENT OF BIOCHEMISTRY

There is a vacancy for a postdoctoral assistant to work on either the genetics or the biochemistry of bacterial sporulation. The appointment, which will be for one year in the first instance, on the scale £3,883 to £6,555 (under review), may be extended for a further period of two years and there is provision for USS membership.

Application, which should include relevant details and the names of two referees, should be sent before May 30, 1979 to Professor J Mandelstam, Microbiology Unit, Department of Biochemistry, South Parks Road, Oxford OX1 3QU 472(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF VETERINARY PHYSIOLOGY

Applications are invited for the post of Lecturer in the Department of Veterinary Physiology. Preference will be given to candidates with experience in teaching physiology and with proven ability to carry out independent research.

Initial salary on the scale £3,883 to £7,754 per annum.

Applications together with the names of three referees, should be received not later than May 31, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref RV/559/N 438(A)

THE DISTILLERS COMPANY LIMITED Yeast and Food Division

MICROBIAL BIOCHEMISTRY

The Yeast and Food Division of The Distillers Company Limited require a graduate to work in areas of Microbial Biochemistry in their research and development laboratories, Glenochil Technical Centre, Menstrie, Clackmannanshire.

Applicants, who should be under 28 years old, must have a degree in microbiology, biochemistry or closely related subjects and preferably have postgraduate experience.

Further details together with an application form can be obtained by writing to: The Yeast Research Manager, The Distillers Company Limited, Yeast and Food Division, Glenochil Technical Centre, MENSTRIE, Clackmannanshire FK11 7ES.

305(A)

Plant Breeding in the tropics

Papua New Guinea is a fascinating country to take up a challenge and a fertile field in which to test your skills, knowledge, adaptability and above all, experience.

Your expertise can add weight to the growing cocoa industry which extends to a number of islands as well as the mainland of Papua New Guinea.

The main role of the post is to carry out a cocoa plant breeding programme including the introduction and development of new disease resistant material, selection, crossing and evaluation on behalf of the Cocoa Industry Board of Papua New Guinea.

Candidates should be honours graduates with a first degree in plant science and relevant post-graduate qualifications and/or several years experience in breeding of tree crops in the tropics. Experience in cocoa breeding would be a very considerable advantage.

The financial rewards are attractive. The basic annual salary will be around £11,500 plus generous gratuities based on length of service starting at 24% of basic salary. Taxation is low, a furnished house and transport are provided and a significant education allowance for children between 9 and 19 is available together with generous leave and air fare provisions.

Applications giving full details of qualifications, career to date and relevant personal details should be addressed in the first instance to Austin Knight Limited, Tricorn House, 51-53 Hagley Road, Edgbaston, Birmingham B16 8TP. Please mark your envelope "Cocoa Industry".

469(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Lecturer in the Department of Zoology. Salary scale £3,883 to £7,754 per annum (under review), with placement according to qualifications and age, and with superannuation benefit.

The successful candidate will be expected to take up duty on October 1, 1979.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, with whom applications (six copies), giving the names of two referees, should be lodged not later than May 5, 1979. Please quote Reference 1032.

400(A)

PROFESSORSHIP IN MOLECULAR GENETICS

Seeking individual for Professorship in Molecular Genetics. Individual must be established investigator for research and teaching in molecular genetics.

Position in Cancer Center with broad laboratory research programmes including cellular genetics and development, tumour immunology, viral oncology, and chemical carcinogenesis.

Salary negotiable dependent on level of experience and academic rank of applicant. Send curriculum vitae and inquiries to: Chairman, Molecular Genetics Professor Search Committee, Cancer Center/Institute of Cancer Research, Columbia University, 701 West 168th Street, New York, New York 10032.

An Equal Opportunity Employer. W60(A)

SCOTTISH INSTITUTE OF AGRICULTURAL ENGINEERING

Head of Basic Cultivations Section
SENIOR SCIENTIFIC OFFICER/PRINCIPAL
SCIENTIFIC OFFICER

(Ref. AG/20)

A vacancy exists for a leader to head the Basic Cultivations Section at the Scottish Institute of Agricultural Engineering, and to be responsible for its day-to-day running. The work involves fundamental research, the design and development of machinery, field trials, and liaison with potential manufacturers on a number of projects in the fields of Basic Cultivation and Farm Transport. Some engineering aids to the sheep farmer may be included. Extensive support services are available (drawing office, workshops, field station, electronics and instrumentation, computing, photography, statistics). The section leader is expected to carry out a personal research programme and will report directly to the Head of the Agricultural Department.

Candidates should have a 1st or Upper 2nd class honours degree in engineering or an equivalent qualification, together with experience of engineering research. Agricultural experience or background and membership of an appropriate engineering institution are also desirable.

Appointment in the Grade of Senior Scientific Officer (£5,154 to £6,898) or Principal Scientific Officer (£6,609 to £8,461) according to experience. Non-contributory superannuation scheme.

Applications and further particulars from the Secretary, Scottish Institute of Agricultural Engineering, Bush Estate, Penicuik, Midlothian, EH26 0PH, to whom applications should be submitted by May 8, 1979.

434(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF PHYSICS

Applications are invited from suitably qualified candidates for a temporary post of RESEARCH FELLOW in the above Department under the auspices of the ICI Joint Research Scheme. The successful applicant would undertake research on molecular conformations and orientation in an active research group studying the properties and microstructure of polymers. The appointment will be made for a fixed period of three years. Applications are encouraged from those who will be available to start on or before October 1, 1979.

Salary on the IA scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 52/4/D. Closing date for applications May 21, 1979.

463(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London) Denmark Hill, London SE5 8RX THROMBOSIS RESEARCH UNIT RESEARCH MEDICAL LABORATORY SCIENTIFIC OFFICER

Applications are invited from recently qualified graduates or candidates holding H.N.D./M.I. Biol or equivalent qualification for the post of Research Medical Laboratory Scientific Officer.

Work will involve investigation of platelet vessel-walled interaction using a variety of *in vitro* techniques. Experience in a biochemical or pharmacological laboratory would be an advantage.

Salary c £3,500 according to qualifications and experience. For further information please contact Dr J Westwick on 01-274 6222, Ext 2913.

Applications, giving full curriculum vitae and the names and addresses of two referees should be sent to the Secretary of the Medical School as soon as possible.

448(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF SOIL SCIENCE RESEARCH ASSOCIATE

Applications are invited for the post of Research Associate in the Department of Soil Science to work on chemical and selected physical problems of using soil covers in the reclamation of colliery spoil. The post, which is supported jointly by the Department of the Environment and the European Economic Community, has assured tenure until December 1980.

The appointment will be made at the appropriate point on the Range IA scale for research and analogous staff: £3,883 to £6,555 per annum, according to age, qualifications and experience. Membership of the appropriate university superannuation scheme will be required.

Further particulars may be obtained from the Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (two copies) with brief curriculum vitae and the names and addresses of two referees, should be lodged not later than May 12, 1979. (Please quote reference Agric. 167.)

481(A)

UNIVERSITY OF CAMBRIDGE

Applications are invited for office of University Demonstrator (equivalent to Assistant Lecturer) in PHYSICAL CHEMISTRY as soon as possible. Person appointed, apart from undertaking normal teaching duties, expected to initiate research in solid state chemistry. Appointment for three years, with possibility of reappointment for two years.

Salary in scale from £4,133 to £5,127 per annum. Higher scales, forming the second part of the rectification of the anomaly in the remuneration of University teachers, have been agreed for introduction with effect from October 1, 1979. Negotiations are also at present proceeding for a cost-of-living increase to have effect from October 1, 1978.

Further information from Secretary of Appointments Committee, Faculty of Physics and Chemistry, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, to whom candidates should send applications (three copies) together with names and addresses of not more than three referees, to reach him not later than May 9, 1979.

500(A)

UNIVERSITY OF SOUTHAMPTON SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES GRADUATE RESEARCH ASSISTANT

Applications are invited for appointment as a Graduate Research Assistant in the Neurophysiology Group of this School, to work with Dr H V Wheal on aspects of the physiology and pharmacology of the crustacean neuromuscular junction. Applicants should have a good honours degree in physiology, pharmacology or related discipline and have an interest in neurophysiology.

The salary will be within £3,384 to £3,883 p.a. (award pending) on scale 1B for research and analogous staff, U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH by May 3, 1979, quoting reference 1063/R/Na.

482(A)

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS AL5 2JQ CHEMIST or PLANT SCIENTIST

with strong interest in plant nutrition required in Soils and Plant Nutrition Department, for work on soil-plant relationships of trace metals, in relation to both deficiencies and pollution problems.

Qualifications: 1st or upper 2nd class honours degree in agricultural chemistry, soil science or a plant science, and preferably postgraduate experience in plant nutrition.

Appointment in grade of Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448). At least two years' relevant postgraduate experience is required for appointment as H.S.O. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 392 by May 18. Further details on request.

458(A)

INSTITUTE OF ORTHOPAEDICS (University of London). RESEARCH ASSISTANT, Honorary Graduate in Biology, to participate in research into human hip disease. Suitable for M.Phil/Ph.D. Three-year Arthritis & Rheumatism Council grant. Information from and applications to the Secretary, Institute of Orthopaedics, Brockley Hill, Stanmore, Middlesex HA7 4LP, with names of two referees.

487(A)

An investigatory and advisory role for Pharmacists

£4,850-£7,585

These posts within the Scientific and Technical Branch of Supply Division offer the opportunity to join a professional, London-based team providing advice, information and consultancy services to pharmaceutical and related departments in hospitals, to the pharmaceutical and medical supplies industries, and to government organisations (both at home and abroad).

The wide range of work undertaken includes participating in the development of national and international standards, promoting research and development of new and improved pharmaceuticals and medical equipment, advising hospitals on the selection and use of such products, and liaising between industry and the N.H.S. on users' needs and problems. Presentation of papers at professional conferences is encouraged.

The current vacancies are concerned with pharmaceutical supplies and sterile single-use medical

devices including renal dialysis and blood transfusion equipment. The work involves the inspection of manufacturing facilities and quality control procedure both in the UK and abroad. Assessment of products includes suitability for intended use, the biocompatibility of materials, stability and mechanical safety, and packaging and sterilisation methods.

For more information about the work, telephone Dr Kay (ext 3379) or Miss Robotham (ext 3124) on 01-636 6811.

Candidates must have a degree (or equivalent qualification) in Pharmacy or a closely related field, and relevant professional experience preferably including some in the manufacture or control of pharmaceutical or medical products or in their procurement in the N.H.S.

Starting salary between £4,850 and £7,585 depending on qualifications and experience. Salary under review. Promotion prospects: Non-contributory pension scheme.

For full details and an application form (to be returned by 17 May 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68651 (answering service operates outside office hours). Please quote 7/5060/2. 433(A)

Department of Health and Social Security

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY RESEARCH OFFICER— ANALYTICAL CHEMIST

We are seeking an energetic Analytical Chemist with a sound background in trace metal analysis and laboratory management experience. Duties include training and some teaching in analytical procedures, method research and development.

Minimum qualifications B.Sc. (Chemistry) or equivalent. Commencing salary, in the range £3,883 to £6,555 plus London Allowance, depending on age and experience.

For details and application form contact Dr I. Thornton, Applied Geochemistry Research Group, Geology Department, Imperial College, London SW7 2BP. 491(A)

QUEEN MARY COLLEGE University of London ASTRONOMY—APPLIED MATHEMATICS

Applications are invited for posts with Professor I. W. Roxburgh on the following S.R.C. supported projects:

(a) POSTDOCTORAL RESEARCH ASSISTANT for three years, using the Distributed Array Processor to study problems of convection and turbulence in the sun and stars.

(b) RESEARCH ASSISTANT/RESEARCH PROGRAMMER for two years to work on (1) Numerical Models of the Solar Wind, and (2) Numerical Simulation of space experiments to test theories of gravity. Initial salary in range (under review) £3,883 to £4,382 per annum plus £502 London Allowance.

Applications, including age, qualifications and experience and names of two referees as soon as possible to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 494(A)

SHRINERS HOSPITAL FOR CRIPPLED CHILDREN Montreal, Canada POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of postdoctoral research assistant in the Joint Diseases Laboratory. The applicant should possess a Ph.D. in Biochemistry or a closely related subject, and preferably have gained experience in techniques for studying the structure of biological macromolecules. The project will be concerned with investigating the structure of the complex protein-polysaccharides (proteoglycans) present in hyaline cartilage.

The post is available for an initial period of two years, with a starting salary of \$14,000. Applications, with curriculum vitae, should be sent to Dr P. Roughley, Joint Diseases Laboratory, Shriners Hospital for Crippled Children, 1529 Cedar Avenue, Montreal, Quebec, Canada. W68(A)

UNIVERSITY OF CAMBRIDGE LUCASIAN PROFESSORSHIP OF MATHEMATICS

Applications invited for the above Chair which will become vacant on September 1, 1979, by the resignation of Professor Sir James Lighthill. Candidature is limited to persons whose work is connected with some aspect of Applied Mathematics and Theoretical Physics and the Professor will be accommodated in the Department of Applied Mathematics and Theoretical Physics.

Present pensionable stipend (under review) £10,939.

Applications (10 copies) marked 'Confidential' should be sent to the Secretary General of the Faculties, from whom further information may be obtained, at the General Board Office, The Old Schools, Cambridge CB2 1TT. Names of two referees may be submitted if desired. Closing date, May 25, 1979. 475(A)

Athrofa Gogledd-dd Cymru The North E Wales Institute of Higher Education

POSTDOCTORAL SCIENTIST

Applications are invited for a postdoctoral research post to work on Lipid Oxidation in Milk Products. The appointment will be for at least two years, with salary in the range £3,910 to £4,408 per annum plus superannuation. The work is sponsored by the Dairy Industry and will be undertaken at the North East Wales Institute, under the guidance of Dr J. C. Allen.

Applications should be made before May 11, 1979, to The Institute Registrar, North East Wales Institute of Higher Education, Keirsterton College, Connah's Quay, Deeside, Clwyd, giving full details of qualifications and experience, also the names of two referees. 485(A)

TECHNICIAN/RESEARCH OFFICER

required for Tumour Virology Laboratory, for work involving tissue culture (preparation of primary cultures and handling of normal and virus-infected cell lines), virus assays, cytological techniques (cell fusion, karyology) and nucleic acid biochemistry (DNA extraction, enzyme assays, hybridisation). The technician will share routine laboratory duties but would also work on research projects without day-to-day supervision.

Degree/HNC required plus at least two years relevant laboratory experience. Salary range £3,582 to £4,902 plus L.W. Appointment available May 1979. For application form write or telephone Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, W.C.2 on 01-242 0200 ext 305. 412(A)

SCIENCE MUSEUM ASTRONOMY

Assistant Keeper

... to take charge of the Astronomy Collection and either the Meteorology or Geodesy and Surveying Collection.

The work includes the acquisition of new material to fill gaps in the existing collections and to expand the modern astronomy section; preparing various publications; assisting the serious student of the collections; maintaining and expanding liaison with university and government departments and with industry. The successful candidate will be expected to become a recognised authority on aspects of the collection. Opportunity to present papers to conferences, at home and abroad.

Candidates must have a degree with first or second class honours (or equivalent) which includes astronomy and either meteorology or surveying. They should have a sound knowledge of modern astronomy, an imaginative approach and the ability to communicate clearly and concisely with non-specialists. Postgraduate degree, and working knowledge of French, German or Latin, advantageous.

Salary: as AK First Class £5,915—£8,875; AK Second Class £3,635—£5,365. Level of appointment and starting salary according to age, qualifications and experience. *Salaries under review.* Non-contributory pension scheme.

For full details and application form (to be returned by 10 May 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote G(22)382.* 436(A)

UNIVERSITY OF ABERDEEN DEPARTMENT OF BACTERIOLOGY LECTURESHP

Applications are invited for the above post from suitably qualified graduates in medicine or science. The Department has interests and facilities in Bacteriology, Virology and Immunology. The successful candidate will participate in the diagnostic service, undertake research, and take part in teaching of medical and science students.

Salary scales (under review): Clinical £4,298 to £7,696; Non-clinical £3,883 to £7,754. Appropriate Honorary Hospital Status would be sought.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by 18 May, 1979. 452(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF BOTANY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistantship to work on the synthesis of enzymes of nitrogen assimilation in wheat. The post, which is supported by the Rank Prize Funds, is for a period of three years from October 1, 1979. The salary will be on the scale 1A, starting at £3,883 p.a.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr J. C. Gray, Department of Botany, University of Cambridge, Cambridge CB2 3EA, from whom further particulars may be obtained. 453(A)

UNIVERSITY OF QUEENSLAND Brisbane, Australia DEPARTMENT OF MINING AND METALLURGICAL ENGINEERING POSTDOCTORAL RESEARCH ASSOCIATE

To study phase transformations in inorganic materials with special reference to reactions of gases with metal oxides. Research, to be carried out under the supervision of Dr P. Hayes, will involve studies of both reaction kinetics and product morphology.

Applicants should hold or be about to complete a Ph.D. in Metallurgy or Physical Chemistry; experience in computing and electron microscopy desirable. Starting date as soon as possible.

Salary SA13,083 to SA14,987. Assistance with travel is available for successful overseas applicant.

Applications, quoting reference No. 15179, with curriculum vitae and the names of two referees, should be sent as soon as possible to The Staff Officer, University of Queensland, St Lucia, Queensland, 4067, Australia. 451(A)

UNIVERSITY OF LIVERPOOL ORTHOPAEDIC AND ACCIDENT SURGERY TECHNICIAN

for research project concerning the biological approach to replacement of arthritic joints. Facilities are available for cartilage and bone cell culture. Previous experience of immunological techniques desirable, but training given. Candidates must possess H.N.C. or an appropriate equivalent qualification and have had several years' laboratory experience. Salary within a range up to £4,056 per annum according to qualifications and experience. Application forms available from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/558/N. 439(A)

MEDICAL RESEARCH COUNCIL TOXICOLOGY UNIT NEUROPHYSIOLOGIST

A neurophysiologist is required to initiate a research programme on the mechanisms of action of toxic substances on the central nervous system. Experience in electrophysiological recording in rodents would be an advantage.

The appointment will be temporary but for a term of at least three years. Salary on M.R.C. Scientific Staff scales depending on age and experience. Applications, together with a full curriculum vitae and the names of two professional referees, should be lodged with The Director, M.R.C. Toxicology Unit, Woodmansterne Road, Carshalton, Surrey SM5 4EF. 474(A)

UNIVERSITY OF OXFORD DEPARTMENT OF PSYCHIATRY MEDICAL LABORATORY SCIENTIFIC OFFICER

A Medical Laboratory Scientific Officer is required for two years to assist with research in clinical pharmacology of psychotropic drugs. The work involves analysis of drugs and hormones in biological fluids. The techniques used include radioimmunoassay, GLC, and HPLC.

The person appointed should have a degree, and H.N.C. or an equivalent qualification preferably in chemistry or a related subject. Salary on Whitley Council M.L.S.O. scale £3,261 to £4,680 per annum.

Application with Curriculum Vitae and the names and addresses of two referees to Mr M. Franklin, Department of Psychiatry Research Unit, Littlemore Hospital, Oxford OX4 4XN. 473(A)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSICS RESEARCH DEMONSTRATOR

Applications are invited for the post of Research Demonstrator in the Department of Physics. He/she will be required to undertake, under the direction of the Head of Department, tutorial or demonstrating work within the Department up to a maximum of twelve hours a week; he/she is not expected to give lecture courses. The successful applicant will be required to work for the degree of Doctor of Philosophy. Preference will be given to candidates who wish to do research in the field of disordered matter or metal surfaces but those with related interests would also be considered.

Salary within the range £3,215 to £3,384 to £3,634.

Further particulars and application forms obtainable from the Registrar. 466(A)

UNIVERSITY OF OXFORD POSTDOCTORAL SCIENTIFIC ASSISTANT

Applications are invited for a post-doctoral scientific assistant position (awarded to January 31, 1982) on an M.R.C. Programme Grant concerned with studies on the endocrine control of parturition in sheep and man. Previous experience of separation techniques for protein and steroid hormones would be an advantage but is not essential. Salary on the scale £3,383 to £6,555.

Applications giving details of qualifications and experience, together with the names and addresses of two referees should be sent to Professor A. C. Turnbull, Nuffield Department of Obstetrics and Gynaecology, John Radcliffe Hospital, Headington, Oxford OX3 9DU. Closing date for applications May 12, 1979. 471(A)

The Research Division of Synthelabo located in
PARIS
requires a
SENIOR CARDIOVASCULAR PHARMACOLOGIST
to join its Department of Biology

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

For this key position in the Cardiovascular Group we require a professional and highly motivated scientist who will be responsible for various projects within the group and should also be able to conduct independent research programmes.

Applicants can be either male or female and should have relevant postdoctoral experience (a maximum of five years). It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent directly to:

Only candidates under serious consideration will be contacted.
W65(A)

UNIVERSITY OF WESTERN AUSTRALIA Perth TUTORSHIP IN MICROBIOLOGY

Applications are invited for the above appointment which will be for a period of three years. The minimum qualifications are a B.Sc. degree with Honours. Duties include the responsibility of demonstrating for Science, Agriculture and Dental Science undergraduate laboratory classes, as well as the co-ordination of these programmes and tutorials within the total teaching programme. Current total student numbers are approximately 160 from 2nd and 3rd year levels. Current salary range: \$A11,220 to \$A13,210 per annum. The appointee will be entitled to fares to Perth for self and fully dependent family and to a removal allowance, and to similar return benefits to place of engagement on completion of three years' service.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by May 12, 1979. Candidates should request three referees to write immediately to the Staffing Officer.

480(A)

JOHN INNES INSTITUTE DEPARTMENT OF APPLIED GENETICS

Applications are invited from geneticists with interests in the development and physiology of higher plants to work on the control of the determinate habit in peas.

This project will be of direct relevance to the Institute's programmes on the production of new varieties of leafless peas and Rhizobium genetics, and will interrelate with other studies on the physiology and seed protein biochemistry of peas. Further particulars may be obtained from Professor D. Roy Davies.

Appointment will be as Higher Scientific Officer (£4,101 to £5,448) or Senior Scientific Officer (£5,154 to £6,898), grade and starting salary depending on experience. At least two years' relevant postgraduate experience is required for appointment as Higher Scientific Officer, with four years for Senior Scientific Officer. Preference will be given to candidates with a Ph.D. in Genetics. Non-contributory superannuation.

Applications, quoting reference AG/35, giving full particulars and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH, not later than May 11, 1979.

488(A)

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS. AL5 2JQ

Applications are invited from suitably qualified scientists for the post of Head of the Insecticides and Fungicides Department to succeed Dr I. J. Graham-Bryce, who has been appointed Director of East Malling Research Station, with effect from August 1, 1979.

The Insecticides and Fungicides Department has over 50 scientific staff and receives many visiting workers. The scientist appointed will be expected to lead a multidisciplinary research programme seeking to make the chemical control of pests and diseases more effective and safer.

Appointment in the grade of S.P.S.O. £10,043 by two increments to a maximum of £11,300. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees, and quoting Ref. 385 by June 1, 1979. Further details on request.

456(A)

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS. AL5 2JQ AGRONOMIST/CHEMIST

required in the Soils and Plant Nutrition Department to join a small team working on a varied programme of field experimentation and associated laboratory work, mainly concerned with fertilisers and plant nutrition.

Degree, H.N.C. or equivalent qualification in soil science, agricultural chemistry or agricultural science, experience of field experimentation would be an advantage, and a driving licence is essential.

Appointment in grade of Scientific Officer (£2,839 to £4,415), or Higher Scientific Officer (£4,101 to £5,448). Acceptable post-qualifying experience is required for appointment to the higher grade. Starting salary according to qualifications and experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees, and quoting Ref. 381 by May 11, 1979. Further details on request.

455(A)

UNIVERSITY OF GLASGOW DEPARTMENT OF ELECTRONICS AND ELECTRICAL ENGINEERING RESEARCH POST IN INTEGRATED OPTICS

A post financed by an S.R.C. Research Grant, tenable until September 30, 1981, is now available for a person with a background in experimental solid-state chemistry or materials science to work with a large integrated optics group on electro- and acousto-optic devices. Starting salary up to £5,129 (interim) within Range 1A of the salary scale for Research and Analogous Staff.

For further particulars write to Professor John Lamb, Department of Electronics and Electrical Engineering, University of Glasgow G12 8QQ, to whom applications (two copies) should be addressed, giving the names and addresses of at least two Referees. Closing date May 25, 1979.

In reply please quote Ref. No. 4429M.

462(A)

QUEEN MARY COLLEGE University of London FLUID MECHANICS ON THE DISTRIBUTED ARRAY PROCESSOR

The Distributed Array Processor, a fundamental development in computer architecture, is particularly suited to solving the Navier-Stokes equations for fluid motion. S.R.C. is funding research here into the Large Eddy Simulation of turbulence and has awarded a grant for application of the DAP to this work. Applications for this post are invited from those with relevant experience of large programmes (DAP uses a variant of FORTRAN); preference will be given to those with a knowledge of fluid mechanics.

Initial salary in range (under review) £3,883 to £4,382 per annum plus £502 London Allowance. Further details obtainable from Professor D. C. Leslie, Nuclear Engineering Department, while applications, with curriculum vitae, publications and names of two referees, should be sent to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS.

493(A)

MAX-PLANCK-INSTITUT FÜR BIOCHEMIE AT MARTINSRIED NEAR MUNICH

The
Deutsche Stiftung für Krebsforschung,
together with the
Max-Planck-Gesellschaft zur Förderung der
Wissenschaften e.V.,

offers

A YOUNG SCIENTIST

the opportunity to set up a research group in the above institute in the field of basic, medically oriented tumor research and to conduct his/her research programme independently.

Fields of activity of the institute are biochemistry, physical biochemistry, molecular biology, structure research, genetics, cellular biology, and virus research. There also exist good opportunities for cooperative links with clinics.

Applicants should already have accomplished internationally recognised research; their special field of research should fit into the frame of the institute's activities.

Work should start at the earliest possible date. The appointment salary will be made for an initial period of five years. The salary will be calculated according to group AH3 of the Niedersächsische Besoldungsgesetz.

The group will be provided with up to two positions for German or foreign scientific co-workers and with up to three positions for technical staff. It will be given its own laboratory, appropriate equipment and adequate operating funds.

Applications should include a tabular curriculum vitae, a list of publications, and a short description of scientific work, both achieved and intended, and should be sent to

Dr. Mildred Scheel — Deutsche Stiftung für Krebsforschung
— Villa Hammerschmid — D-5300 Bonn-Bad Godesberg — no
later than May 31, 1979. W64(A)

Universiteit van Amsterdam

Applications are invited for a teaching and research post

lecturer (m/f)

(wetenschappelijk medewerk(st)er)

in the Department
of Structural Geology.

Duties will include: (1) courses of lectures and practicals in the microstructural interpretation of the relationship between deformation and metamorphism, and of deformational mechanisms, (2) research in the field of structural geology, and (3) help with general teaching and administrative duties in the Department.

Salary in accordance with background and experience, Ph.D. required.

Applications, with curriculum vitae, precise research interests and the names of at least two referees, should be sent to
Dr. O. J. Simon, Geologisch Instituut,
Nieuwe Prinsengracht 130,
1018 VZ Amsterdam, The Netherlands,
before June 1st 1979.

W63(A)

FELLOWSHIPS

UNIVERSITY OF SUSSEX

SCHOOL OF MATHEMATICAL AND PHYSICAL SCIENCES ASTRONOMY DIVISION RESEARCH FELLOWSHIP IN OBSERVATIONAL EXTRAGALACTIC ASTRONOMY

Applications are invited for a Postdoctoral Research Fellowship in Observational Extragalactic Astronomy, to commence as soon as possible after October 1, 1979. The post will be for two years, with possible extension to a third.

The Research Fellow (M/F) will be expected to collaborate with the other observational Research Fellows at the Astronomy Centre, and with visiting faculty members based at the Royal Greenwich Observatory in carrying out spectrometric and photometric observations of extragalactic radio and X-ray sources and peculiar galaxies in general in the Southern Hemisphere.

Commencing salary will be in the range £3,883 to £6,555 per annum (under review), with U.S.S. benefits.

Further information can be obtained from Professor L. Meisel, Astronomy Centre, Physics Building, University of Sussex, Falmer, Brighton BN1 9QH, to whom applications, and the names of three referees, should be sent by May 31, 1979. 445(E)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF PHYSICS RESEARCH FELLOWSHIPS IN CRYOGENICS

Applications are invited for Postdoctoral Fellowships to work on the following projects:

1. Heat transfer in the reboiler/condensers of cryogenic plant, using model rigs and a full length test section.
2. Complex convective flow in stratified cryogenic vapours and liquids using Laser Doppler Anemometry.
3. Heat transfer and fluid behaviour of helium at 3,000 r.p.m. for the development of large superconducting machines.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salary in range up to £5,367 plus U.S.S. benefits.

Applications with names of two referees should be sent to Mrs E. C. P. Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH. Please quote reference number 1607/R/N. 441(E)

BRANDEIS UNIVERSITY Rosenstiel Center

A postdoctoral fellowship is available for the study of structure and assembly of tobacco mosaic virus by X-ray diffraction from oriented gels. Extension and refinement of present 4 Å structure, study of other helical TMV protein aggregates and of related viruses. Project is related to larger program of Dr D. L. D. Casper on virus structure. Computing ability is desirable and preferably crystallography, protein chemistry or biological structure experience. Available immediately, for up to two years \$12,500-\$15,000.

Contact Dr G. Stubbs, Rosenstiel Center, Brandeis University, Waltham, MA. 02154, USA. (617)-647-2467 W55(E)

THE ROYAL SOCIETY The Smith & Nephew Foundation SENIOR RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for The Royal Society Smith & Nephew Foundation Senior Research Fellowship, established by means of a five-year grant from the Smith & Nephew Foundation for research in organic chemistry or biochemistry. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged). Applicants should be under 40 on October 1, 1979. The present stipend scale is £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by June 4, 1979. 443(E)

FLINDERS UNIVERSITY OF SOUTH AUSTRALIA SCHOOL OF BIOLOGICAL SCIENCES POSTDOCTORAL RESEARCH FELLOWSHIP IN VIROLOGY

Applications are invited for a Postdoctoral Research Fellowship in the Microbiology Group of the School of Biological Sciences. The successful applicant will work with a small group studying the biochemistry of the anti-tumour action of interferon, with particular reference to the role of 2'-5' polyadenosine oligonucleotides in mediating the growth-inhibitory properties of interferon. Experience with interferon biochemistry, nucleotide chemistry or cell-cycle biology, while not essential, would be an advantage.

The Fellowship (funded by the Anti-Cancer Foundation) is available immediately and is renewable on an annual basis until December 1981. Further particulars may be obtained from Professor E. M. Martin of the School of Biological Sciences.

Salary: \$A14,400 to \$A15,586 per annum.

Applications, which should include a full curriculum vitae, list of publications, and the names of at least two referees, should be addressed to The Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042; they should reach Australia by April 27, 1979, but will be accepted for a further seven days. 477(E)

COURSES

HAZARD ANALYSIS

A Post Experience Course will be held at Imperial College from June 25 to 28, 1979. Details from Dr D. H. Napier, Chem. Eng. and Chem. Tech., Imperial College, London SW7 2BY. Tel 01-589 5111, Ext. 1906 448(D)

STUDENTSHIPS

HILL FARMING
RESEARCH
ORGANISATION
A.R.C. RESEARCH
STUDENTSHIP

Applications are invited for an Agricultural Research Council Studentship tenable for 3 years from October 1, 1979 at the Hill Farming Research Organisation for research leading to a higher degree. The research topic to be investigated concerns the nutritional and animal performance consequences of the type, composition and amount of supplementary feeding given to pregnant sheep grazing hill vegetation in winter.

Applicants should possess, or expect to obtain, a 1st or Upper 2nd class honours degree in Agricultural Science or a related subject.

The award which is under review comprises a tax free maintenance allowance according to circumstances (£1,610 per annum for a single person living in rented accommodation) approved University Fees, some travelling expenses and dependent allowances where appropriate.

Further details and application forms can be obtained from the Secretary, Hill Farming Research Organisation, Bush Estate, Penicuik, Midlothian EH26 0PY. Applications should be received by May 11, 1979. 432(F)

LANCHESTER
POLYTECHNIC
AT
COVENTRY
FACULTY OF
APPLIED SCIENCE
DEPARTMENT OF
BIOLOGICAL SCIENCES
N.E.R.C. C.A.S.E. RESEARCH
STUDENTSHIP

THE JOB, to work on the respiratory, physiology and energetics of Antarctic protozoa. The project will be jointly supervised by the Department of Biological Sciences at the Polytechnic and the Life Sciences Division of the British Antarctic Survey.

REQUIRED applicants should have, or expect to obtain, a first or upper second class honours degree in biological science and an interest in ecology, soil microbiology or invertebrate zoology.

For application form and job specification please apply in writing enclosing a large stamped and addressed envelope to the Personnel Officer, Lanchester Polytechnic, Priory Street, Coventry. (Informal enquiries to Dr H. G. Smith, telephone (0203) 24166, Ext. 629) returnable by Friday, May 4, 1979. 470(F)

UNIVERSITY OF
NEWCASTLE UPON TYNE
M.R.C. RESEARCH
STUDENTSHIP

Applications are invited from good honours graduates in a biological science and from students expecting to graduate in 1979 for an M.R.C. research studentship to study myofibre regeneration in muscular dystrophy in man. The work will involve quantitative techniques of electron microscopy, light microscopy and, possibly, tissue culture, and will be carried out at the Muscular Dystrophy Research Laboratories at Newcastle General Hospital in association with Dr M. J. Cullen.

The studentship (value £1,610 per annum) is tenable for three years and the successful candidate will be registered for the degree of Ph.D.

Applicants should write to Dr M. J. Cullen, Muscular Dystrophy Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne, enclosing a curriculum vitae and the names and addresses of two referees, by May 14, 1979. 460(F)

Agricultural Research Council
FOOD RESEARCH INSTITUTE
A.R.C. RESEARCH
STUDENTSHIP

Applications are invited for an Agricultural Research Council Research Studentship, tenable for up to three years from October 1979, in the Nutrition and Food Quality Division of the A.R.C. Food Research Institute.

The research will be conducted under the supervision of Dr D. A. T. Southgate on one of the following topics.

(a) The behaviour of complex polysaccharides in the small intestine with special reference to the effects of the unavailable carbohydrates (dietary fibre) on digestion and adsorption.

(b) The characterisation of the microbial fermentation of dietary fibre in human foods.

Candidates should hold or expect to gain this summer a first or upper second class Honours degree in a relevant discipline and the successful candidate will be expected to register with the University of East Anglia for a higher degree.

Further details and application forms (to be returned not later than June 1, 1979) are available from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA. 449(F)

QUEEN MARY COLLEGE
University of London
CHEMISTRY DEPARTMENT
ORGANIC
ELECTROSYNTHESIS

Applications are invited for the following positions, both supported by S.R.C. for work in collaboration with Dr J. H. P. Utley.

C.A.S.E. Postgraduate Studentship—jointly with Phizers Central Research (Sandwich) and involving electrochemical synthesis of pharmaceutically active amines. Usual S.R.C. conditions apply. Candidates should be graduates, or expecting to graduate in 1979, with 1st or upper 2nd class honours.

Postdoctoral Fellowship—for work on enhancing selectivity in a variety of electro-organic syntheses. Previous experience of organic electrochemistry an advantage but good background in organic synthesis would suffice. Appointment for one year in first instance, with possibility of renewal for second year. Initial salary in range (under review) £3,883 to £4,382 per annum plus £502 London Allowance.

Applications, including age, qualifications and experience and names of two referees, as soon as possible to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS. 495(F)

S.R.C. C.A.S.E.
RESEARCH STUDENTSHIP
UNIVERSITY OF
NEWCASTLE UPON TYNE
SCHOOL OF PHYSICS

Applications are invited from persons holding, or expecting to obtain, a good honours degree in physics for a C.A.S.E. studentship in theoretical solid state physics concerning electronic properties of defects in semiconductors, in collaboration with the Royal Signals and Radar Establishment, Malvern.

Further details are available from Dr M. Jaros, School of Physics, The University, Newcastle upon Tyne NE1 7RU, to whom applications should be sent along with curriculum vitae and the names of two referees. 442(F)

UNIVERSITY OF DURHAM
DEPARTMENT OF BOTANY

Applications are invited for an S.R.C. Studentship and Case Studentship available from October 1979 for suitable candidates interested in recombinant D.N.A. methods or the physiology and biochemistry of crop improvement.

Applications giving brief curriculum vitae and naming two referees should be sent by 11 May, 1979, to Professor D. Boulter, Department of Botany, Science Laboratories, South Road, Durham DH1 3LE. 440(F)

UNIVERSITY OF
CAMBRIDGE
DEPARTMENT OF APPLIED
BIOLOGY
M.A.F.F. RESEARCH
STUDENTSHIP

Applications invited from graduates or those expecting to graduate this summer for a Studentship to study the ecology of the carrot fly (*Pila roseae*) with view to establishing a pest management system for its control.

Further details from the Secretary, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX. 498(F)

ASSISTANTSHIPS

LIVERPOOL
POLYTECHNIC
DEPARTMENT OF
PHARMACY
RESEARCH ASSISTANTSHIPS

(Two posts—A and B)
Salary scale £2,511 to £2,967 plus £312 per annum

A *Correlation between Chemical Structure and anti-inflammatory activity*

This project seeks to define the parameters which control anti-inflammatory activity, probably by the use of principal component and discriminant analysis. The post is suitable for a pharmacist or pharmacologist with an interest in data analysis, or a chemist or physical scientist with an interest in the life sciences.

(Informal enquiries to Dr J. C. Deardon, on 051-207-3581, Ext. 45)
B *The metabolism, disposition and activity of some potent phenyl-piperidine analgesics in animal and human subjects*

A post financed by the local education authority is available for a graduate in pharmacy or related fields. (Informal enquiries to Dr K. Chan, on 051-207-3581, Ext. 47)

Applicants for posts A and B should possess or expect to gain a good honours degree and the appointee will be expected to register for a higher degree of the C.N.A.A.

Application forms and further particulars from the Personnel Office, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 9RH Tel 051-227-5581, Ext. 43. Please quote reference LP/281. 464(P)

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSICS

Applications are invited from an electronics engineer or physicist with an electronics background for a senior research assistantship tenable for two years, from as soon as possible. The work will involve the development of silicon diode arrays for low light level imaging in astronomy and their associated data acquisition systems. Experience with minicomputer systems would be an advantage.

Initial salary in the range £3,883 to £5,129 (under review) on range 1A plus superannuation.

Applications (three copies) naming three referees should be sent by May 11, 1979 to the registrar and secretary, Science Laboratories South Road, Durham DH1 3LE, from whom further particulars may be obtained. 410(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF
CHEMISTRY

Applications are invited from chemists, materials or poly scientists, or solid state physicists an S.R.C. funded postdoctoral Science Research Assistantship tenable for years from October 1, 1979 (or earlier by arrangement) for an interdisciplinary investigation of the formation and properties of thin films of structure and reactivity of polymers, systems, and composites in general primarily by ESCA. The appointee will assist in setting up a cur designed spectrometer dedicated to research.

Salary £3,883 to £4,133 on range 1A plus superannuation.

Applications (three copies) naming three referees should be sent by 1.1.1979 to the Registrar and Secret Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 411(C)

UNIVERSITY OF
CAMBRIDGE
DEPARTMENT OF BOTANY
GRADUATE RESEARCH
ASSISTANT

Applications are invited for a graduate research assistantship to work the synthesis of components of photosynthetic electron transfer in higher plants. The post, which is supported by the Science Research Council, is for a period of three years from 1 October, 1979.

The salary will be on the scale starting at £3,384 per annum. A suitable applicant may be able to register for the degree of Ph.D.

Applications with curriculum vitae and the names and addresses of referees should be sent as soon as possible to Dr J. C. Gray, Department of Botany, University of Cambridge, Cambridge CB2 3EA, from whom further particulars may be obtained. 454(C)

SCHOLARSHIPS

UNIVERSITY OF SYDNEY
HENRY BERTIE AND
FLORENCE MABEL GRITTO
RESEARCH SCHOLARSHIP
—SENIOR GRADE

Applications are invited from graduates of universities that members of the Association Commonwealth Universities or graduates of any university who are citizens of a Commonwealth country. Candidates are expected to have a degree or postgraduate research experience.

The Scholarship, tenable at University of Sydney, is available for research in chemistry related to industry and agriculture. A brief outline proposed research project should be included with the application.

The Scholarship at senior level valued at \$A14,400 to \$A14,797 is tenable for one year but may be renewed for a second.

Application forms are available from the Registrar, University of Sydney, N.S.W., 2006, Australia, to whom applications close on June 1979. 485(F)

WORKSHOPS

FMI SYMPOSIUM ON
PROTEIN
PHOSPHORYLATION AND
BIOREGULATION

An interdisciplinary workshop to be held at the Friedrich-Miescher Institut, Basel, Switzerland, December 10 to 12, 1979.

A strictly limited number of places will be available. In application please outline your area of interest and material you may wish to present as a poster. Deadline, August 31.

Applications to Dr Julian Gottfried, Friedrich-Miescher-Institut, P.O. 273, CH-4002 Basel, Switzerland. 466(C)

INTENSIVE CARE FOR YOUR TISSUE CULTURES??

Gallenkamp announce a new CO₂/humidity incubator which they have designed using their expertise to provide the utmost care for your sensitive tissue cultures. Prevention of environmental fluctuations, to which many cultures are sensitive, is necessary for healthy culture growth and therefore emphasis has been placed on close control of the internal atmosphere.

CO₂ concentration is under truly automatic control to allow a rapid response to changes while economising on CO₂ consumption. Both temperature and humidity are also controlled so that cultures are kept in a maintained, optimum environment.

Nursed by the continual regulation, cultures develop correctly and the automation ensures that the only human attention required is initial control setting and occasional replenishment of the liquid in the humidity tray.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if ' a ' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors. (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

ICE AGES

M

: Solving the Mystery Professor John Imbrie and Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' — why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in *ICE AGES*, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"*ICE AGES* is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

INDEXES

The following indexes are still available:

	UK	Rest of World
1971	£5.00	US \$10.00
1972	£5.00	US \$10.00
1973	£5.00	US \$10.00
1974	£5.00	US \$10.00
1975	£5.00	US \$10.00
1976	£5.00	US \$10.00
1977	£5.00	US \$10.00
1978	£5.00	US \$10.00

Listing the year's papers by both author and subject, they assist quick, easy reference to past issues.

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00; Rest of World US \$6.00, three for US \$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

With the moving of many of *Nature's* American activities to our New York office, we lose the services of Mary Wade, our Washington Office Manager, after fifteen years with *Nature*. She spent seven years in London before moving to Washington. Mary has done much more than simply run an office cheerfully and effectively; she has kept the London office in close touch with literally thousands of American scientists and has ensured that *Nature* has responded efficiently to their concerns.

Authors who wish to submit manuscripts to *Nature* by way of our American office should now send them to our New York office—*Nature*, 175 Fifth Avenue, New York, NY 10010.

pour savoir ce qui se passe lisez plutôt La Recherche

How to keep up with what's going on in research, in all the disciplines, throughout the world? How to know what the top research centers are doing?

You can make your own search of the specialized literature — but each year there appear 2.5 million original articles. You don't need to read them all, of course, but the problem is to sort out those that count the most.

Is one solution to sneak around the labs? Hardly an ethical procedure to begin with, it's also silly and inefficient for one to stoop so low. Besides, there's only a back-ache awaiting anyone who wants to be the James Bond of science.

Subscribing to *La Recherche* is much simpler... and far more profitable. An interdisciplinary journal. *La Recherche* offers you each month a round-up of everything important going on in re-

search — from biochemistry to astrophysics. *La Recherche* is an international magazine published in French, but its articles are written by specialists from all over the world.

And they're read throughout the world.

special offer

Mixture as before—to 1984?

IN A week's time the British electorate will instal a new government which could, if returned with a sufficient majority, see the nation through to 1984. The three major political parties, Labour, Conservative and Liberal, each publish brief but comprehensive manifestos regrettably padded out with a tedious mixture of boasts and insults. Somewhere in their midst, however, we ought to be able to discern clear, separate strands of political thinking which differentiate the parties and which when viewed against the current economic and social background give a clear indication of the most appropriate party for the next five years.

What is this background? In the 1970s Britain's industrial production has barely risen at all, whilst that of other major industrialised countries has climbed—in difficult circumstances—by amounts ranging from 15% to 30%. In terms of gross domestic product per capita, 15 years ago Britain was closely on a par with many European countries and nearly a factor three ahead of Japan. Now most of Europe has left us far behind, and Japan is fast doing so too. Only in the inflation league has Britain shown its competitors (with the exception of Italy) a clean pair of heels. All of this has happened to a country not notably short of material and energy resources, and certainly not lacking in human and intellectual resources.

Many argue, quite reasonably, that Britain is still an agreeable country in which to live, that the people are civilised and not driven by the materialist urges that allegedly are rife in other countries. Why, it is said, worry about international growth, productivity and efficiency leagues in such a green and pleasant land? The answer to this must surely be that unless we exert ourselves to the full, competition from other countries will not allow us just to stand still—it will rapidly bring on irreversible decline and the emigration of large numbers of talented people.

With the coming of post-industrial society, in which a diminishing number of people are involved in factory-style production and a growing number in some sort of 'information activity'—teaching, research, entertainment, printing, health, journalism, banking and so on, it is particularly important that flexibility be emphasised. It is almost impossible to envisage what the world will be like in 10 years' time, but one thing is certain: that it will have undergone rapid change, and that unless strong action is taken, a lot of people—indeed whole nations—are going to be left behind.

The strong action must take two forms—first, to permit or even encourage declining industries to die peacefully without deceiving those associated with them into thinking that better times are just around the corner; second, to take much more vigorous steps to promote lifelong education and retraining, so that going back to school or college is seen not as a humiliating thing of last resort, but as a perfectly natural thing to do.

How much of this is hoisted in by the two main political parties—and how much are they prepared to act on it? The Conservatives are probably more capable than Labour of being ruthless with declining industries. But they do not show much sign of recognising the changes that need to be wrought in our educational system beyond stating "we shall review the relationship between school, further education and training to see how better use can be made of existing resources"—which could mean anything. On the whole Labour seems, in its manifesto, to appreciate the changes that are necessary—even putting in a reference to the impact of the silicon chip—but the party has largely presided over the years of industrial decline without doing much to arrest it.

The real source of Britain's dilatory industrial performance cannot be blamed on a scarcity of resources, nor on a lack of intellectual skills. It must be placed squarely on our apparent inability to work together without breaking up into isolated groupings—'workers', 'skilled workers', 'management', 'civil servants', 'academics' and so on, each finding difficulty in understanding the other and each either busy exploiting the others or accusing the others of exploitation. To the extent that the British are naturally sceptical of authority, lack of homogeneity is fine. But the divisions are much more bitter and unproductive than that. Both major political parties exist, indeed thrive on these dichotomies, and so are themselves part of the problem they should be trying to eliminate. This, then, should make the Liberal party an attractive alternative. Certainly the Liberal manifesto touches on many of the matters discussed above, and the party even makes a play for being regarded as the environmental party. Traditionally a vote for the Liberals has been regarded as wasted in the British system of representation. That must not be allowed to deter thoughtful people, worried about an ever-declining, ever-confrontational Britain, from looking very seriously at the Liberals. □

University challenged over 'agribusiness' connections

David Dickson contributes his third weekly article on science in the American West with a report on farm workers in California, who are suing university officials over the social consequences of agricultural research

EARLY next month a county court in California will begin hearings on charges that have been brought against the University of California, claiming that it has carried out agricultural research leading to a variety of undesirable social consequences. These include the disappearance of harvest-time jobs as a result of increased automation, the shift from small family farms to large-scale 'agribusinesses', and the enrichment of corporate stock-holders out of public pockets.

A suit filed by a publically-financed group, California Rural Legal Assistance, on behalf of a number of farmworkers, concentrates in particular on the way that university research has contributed to the growth of mechanised agriculture in the state, resulting, the group claims, in extensive job dislocation and unemployment.

The suit demands that such research be stopped. And it also accuses senior members of the university and its Board of Regents of a conflict of interest over their connections with large food-producing corporations which, it is claimed, have been the principal beneficiaries of state- and federally-financed research.

The university, in response, has strongly denied any impropriety. In a statement issued at the end of last week, university counsel Mr Donald C. Reidhaar said that if the suit succeeded, it would prevent the university from carrying out research which might result in harm to certain people and in help to others.

"A basic mission of the university is research and the creation of new knowledge. Acceptance of the plaintiff's proposition would require the elimination of all research with any potential practical application," Mr Reidhaar said.

Research workers at the University of California have been engaged for more than a hundred years in developing techniques to raise agricultural production; ironically one of the university's first major political crises involved the claim that it was not doing enough of practical assistance to local agriculture.

Much of this research has been related to mechanising traditional agricultural practices, often with state support. In the mid-1960s, for example, the university was awarded an annual grant of \$150,000 by the state legisla-

ture to carry out research into automated farm machinery, following the phasing-out of a programme to bring farm labourers across the border from Mexico at peak harvesting time.

Yet not everyone has appreciated—or benefitted from—these changes. In tomato growing, for example, research at the university's Davis campus has led to developments ranging from automated picking and sorting machines, to a strain of "square tomato" whose thick skin protects it during mechanical processing; but many small farmers who could not afford the expensive new equipment have been forced out of business, while tomato harvesting no longer provides summer-time work for many thousands of migratory workers.

Strong opposition to the increasing automation of agriculture in California—as well as to the university's role in encouraging this process—has come from the United Farm Workers, the union established in the early 1970s after several bloody confrontations with growers. The union is concerned, for example, that many farm owners have used the elimination of jobs to offset the increased wages that the union has been able to negotiate for its members.

"We are not against mechanisation, but do not think that the taxpayer should pay twice, first for the univer-

sity research and then for the increased unemployment, welfare and social service costs" says union official Mack Lyons. Last year the union's convention passed a resolution demanding a moratorium on future research in agricultural mechanisation until it had been assured that the interests of farm workers would be protected.

The legal challenge, however, has come not from the union, but from a group of attorneys working for an organisation set up on state and federal funds to protect the rights of farm workers. In a suit filed in the Alameda County Court, it is demanded that the university stop all research on any agricultural mechanisation process that conveys has "a special economic benefit to narrow, private agribusiness interests at the expense of farmworkers, small family farmers, consumers, taxpayers and the quality of rural life".

By using tax money to benefit a small group of private corporations and by acting out of individual economic self-interest, the plaintiffs claim that the university and various named members of its Board of Regents have acted contrary to the state constitution, which requires that the university be administered as a public trust for the benefit of all Californians, free of political influence.

"We are questioning who benefits from the technological changes resulting from this research, who gets hurt—and who takes the decisions. In this type of situation we feel that there should be an open decision-making pro-

"The machine won't strike, it will work when the growers want it to work"

cess before money is spent on research," says Mr Al H Meyerhoff, one of the attorneys who have filed the suit on behalf of nineteen farmworkers and the California Agrarian Action Project.

"The increasing monopoly over agricultural production of large food-producing corporations is being facilitated by research and development work at public universities initially established, under the land grants colleges legislation, to help small farmers. We feel these institutions should not be contributing to the problems that these farmers face."

The university strongly denies charges that the results of its agricultural research programmes have been socially detrimental. In particular, according to university staff.

- although mechanisation has resulted in declining employment in some areas, this has been largely compensated for both by the introduction of new jobs in other areas, and by other employment opportunities brought about by general increases in agricultural productivity;

- rather than merely benefitting large corporate producers, the technological developments arising from university research have been of general benefit to the community, the advantages of increased productivity for example being passed on through lower food prices,

- and the university is also challenging whether it should have any particular responsibility for the social consequences of its research programmes, or whether this responsibility should not be shared by the whole community.

"The university's responsibility is to create new knowledge or information, to develop new ways to produce food as efficiently as possible, and to be aware of new developments, and so forth. But in terms of the conflict of social goals, that's not only *our* job, but the job of society, of the legislature." Professor Charles Hess, dean of the college of agricultural and environmental sciences, said in a recent interview.

Others at the university strongly support this view, although many admit that the automated machinery that they have developed has been made particularly attractive to local growers by the increasing strength and militant tactics of unionised farmworkers.

"Automatic lettuce harvesters, for example, developed at the university have been available for some time, but have not been widely taken up for a number of reasons, in particular cost. But I don't know how many more lettuce strikes we will have before something happens," says Dr William Chancellor, professor of agricultural engineering at the university of Cali-

fornia's Davis campus

From the union's standpoint, increasing mechanisation is a direct threat to its bargaining capabilities. One tomato grower near Sacramento, the target of an unsuccessful UFW campaign in 1975, subsequently bought an electronic tomato sorter for \$200,000, and was able to reduce his work force from 100 to 28, thus getting rid of "all the troublemakers". As one university staff member has been quoted as saying, "the machine won't strike, it will work when the growers want it to work".

The farmworkers have already received considerable support in their fight against mechanisation from members of the state legislature. At the request of one state representative, for example, the state accounting office is already carrying out an audit of the university's research activities to see if it reveals any "improprieties".

But neither has the university been totally insensitive to its criticisms. In addition to publicising the social value of its research, the university points out that the amount of research into agricultural mechanisation is being decreased, with emphasis shifting, for example, to methods for improving the biological productivity of crops.

The university is also both carrying out research and offering retraining courses aimed at the problems faced by farmworkers who lose their jobs as a result of automation. "We have been accused about not caring about the problems that mechanisation causes, but we are now looking at these too," says Dr Chancellor.

In responding to the charges made by the legal aid group, however, the university has denied that there is anything improper in the close links that it has established with private industry: claims that such links result in an "inordinate influence" on research policy are, it says, subjective assessments based on a particular political viewpoint.

Critics remain unconvinced. They blame the major food producers for the social problems of US agricultural workers—as well as the declining flavour of US food—and accuse the University of California (as well as universities playing similar roles in other states) of direct collaboration in this process.

"It belongs to society as a whole to decide what help people affected by agricultural developments should get, and how much. We should not be expected to do this on our own," says one university spokesman. "We believe that it is a travesty for the government to use tax money, in the form of research grants, to force people out of work and drive small family farmers off the land," says Mr. Meyerhoff. □

Professional bodies lobby to protect US science budget

QUOTING a 25% drop in the proportion of the federal budget devoted to basic research between 1968 and 1978, 40 US scientific societies and higher education associations last week issued a joint statement supporting President Carter's bid for a significant increase in support for basic research in the fiscal year 1980.

The statement is critical of the administration's decision to request virtually no increase in funding for biomedical research through the National Institutes of Health, pointing out that this will mean a decrease of almost 50% in the number of new competitive research grants available.

Apart from this, however, the various organisations put their voices solidly behind President Carter's request for a 9% increase in basic research funding—even accepting that this will be barely sufficient to keep up with inflation—and urges Congress to do the same.

So far, the Congressional response to the budget request submitted in January has been relatively good. The Senate budget committee, for example, having taken a detailed look at the requested science budget, has recommended that it be accepted almost in full, although suggesting cuts in virtually all other areas of public spending.

But there may well be stormy weather ahead. The House of Representatives, for example, in authorising a budget for the National Science Foundation close to the \$1,000 million requested, accepted by 219 votes to 174 an amendment reducing funds for biological, behavioural and social sciences research (and aimed primarily at the last of these) by \$14 million; last year a comparable amendment was rejected 174 to 229.

Immediate cause for concern are imminent floor debates on broad budget resolutions in both the Senate and the House, with various proposals that could affect science funding. A further test will come when key appropriations subcommittees meet to decide on agency budgets later next month.

Keen to prevent a repeat of last year, when a substantial increase in funding for basic research requested by President Carter was cut back by Congressional committees to a level—apart from the NIH—scarcely above inflation, the research community has been busy putting its lobbying act together in Washington.

In issuing a joint statement, the

various higher education, scientific and technological societies said they were taking an "unprecedented step" in presenting to Congress a unified position on the needs of science. They expressed concern at "the lack of a congressional policy in science which would embrace the principles of stable, balanced and controlled investment in basic research".

At a press conference in Washington to coincide with the publication of the joint statement, Dr Derek Bok, president of Harvard University, said that there was no contradiction between President Carter's aims to achieve a balanced budget, and to increase the federal investment in basic research.

"These positions are inextricably related, for out of basic research, if history is any judge, will evolve industrial innovation and growth, more efficient and thus less costly uses of labour, energy and equipment, and better health and security for all," Dr Bok said.

Dr David Saxon, president of the University of California, pointed to the present energy crisis as a "very real example" of what could happen if investment in basic research was allowed to fall behind. "Congress used

foresight in 1954 when it amended that Atomic Energy Act to provide for research and development of alternative energy sources. However a review of the funding record for programmes of basic research reveals a history of peaks and valleys. This lack of sustained commitment has discouraged outstanding talent and blunted national progress."

The need to maintain stability in funding is, in particular, being used to justify demands for further increases in funding for the National Institutes of Health. In announcing that it was requesting a level of funding virtually the same as the current year (the Office of Management and Budget is even said to have suggested a decrease) the administration pointed out that Congress voted last year for a 23% increase in biomedical research support—and that even if this was spread over two years, it would still be comparable to planned increases in other areas over the same period.

Supporters of more funds for biomedical research, however, argue that things are not that simple, and that a stationary NIH budget would introduce instabilities by drastically cutting back on new research starts. "Analysis of

the budget by mechanism reveals a disconcerting and unacceptable reduction in the funds available for young investigators," says Dr Suzanne Oparil of the University of Alabama, chairwoman of the American Federation for Clinical Research.

A marked increase in obligated non-competing research projects supported by NIH would, she says, result in a 43% decrease in funds available for competing research projects. "Because young biomedical investigators are supported primarily by investigator-initiated competing research grants, this reduction in funds for competing grants must be vigorously opposed."

Biomedical research workers are particularly concerned that although in previous years Congressional committees have traditionally provided significant increases to medical research, the current mood against further public spending—together with the loss of several key Congressmen, such as Senator Edward Brooke and Representative Paul Rogers, who had previously championed the medical research cause—mean that a comparable increase this year is far from guaranteed.

David Dickson

US accused of banning foreign scientists

FOREIGN scientists invited to lecture or participate in scientific meetings in the US continue on occasion to suffer the embarrassment of being denied entry to a country "proud of its right to freedom of speech", according to a senior member of the American Association for the Advancement of Science.

This situation arises because those taking part in scholarly and cultural exchanges whose political beliefs fall into particular categories—and in particular past or present members of the Communist party—must obtain a special waiver from the State Department to obtain a temporary entry visa.

"In general this policy has been implemented in a liberal way so as to remove automatic exclusion of foreign scientists and others who might express beliefs or support for political doctrines previously restricted by our immigration laws," Professor John Edsall, chairman of the Committee on Scientific Freedom and Responsibility, told a Congressional committee studying US compliance with the Helsinki Agreement earlier this month.

"However in some cases the policy has remained unchanged, or foreign visitors have been excluded on grounds other than political beliefs, thus making the waiver procedure more difficult to implement. What is most desirable from the view of scientists is the removal of these restrictions from

the US immigration laws."

Professor Edsall, who is professor emeritus of biochemistry at Harvard University, listed a number of cases which, he said, appeared to violate the principles of free travel as stated at Helsinki, instances in which political or administrative decisions had impeded the free circulation of scientists. These included:

- The refusal of a visa application—later granted—to Dr Sylvia Berman, an Argentine psychologist now living in exile in Mexico city who is alleged to have previously expressed Marxist beliefs, to participate in a meeting of the American Public Health Association in Washington DC, last year.

- The denial of a visa in 1975 to Dr Joseph Needham, the British science historian. Although the state Department informally acknowledged that this was because of his allegedly Marxist beliefs, it refused to provide him with the reason for the denial. Dr Needham subsequently refused to apply for a waiver. On subsequent visits, Dr Needham has been granted a visa without having to apply for a waiver.

- Late last year, delays in reviewing the visa application of Professor Jean Pierre Vigier, a French physicist who had been invited to address the AAAS annual meeting in Houston, Texas, made it impossible for him to attend the conference.

- Dr Andre Frank, professor in the

school of development studies at the University of East Anglia, although previously a US resident, has consistently been denied a visa on various grounds, both regarding his political affiliations and unspecified evidence—which Dr Frank denies—that he may wish to take up residence in the US again.

Professor Edsall said that other areas of concern involved the controls placed on the travels of foreign scientists while visiting the US, since the State Department has divided the country into open and closed areas as part of our diplomatic relations with the Soviet Union and East European countries.

"It appears questionable at the present time whether such a travel restriction policy will also be applied to the Chinese scientists, who are currently seeking expanded scientific exchange with the US. In the interests of science it is important to promote free access to all individuals who wish to exchange information, without arbitrarily assigning the need for screening or political controls", he said.

"Our violations are, I would agree, a good deal less serious than those that have occurred and still occur, in countries with Communist governments; but let us do away with them and show that we truly honour the spirit of the Helsinki accords."

David Dickson

Soviets boost their own . . .

LAST week, the Soviet Union celebrated its new "Science Day" (the third Sunday in April). To mark the occasion, *Pravda* published an extensive article by Academician Anatolii P. Aleksandrov, President of the Academy of Sciences, which, while praising, naturally, the achievement of Soviet science, did so largely at the expense of the West.

The new Soviet "Science Day", of course, has considerable political overtones. The date was chosen to commemorate 12 April, 1918, when the Soviet of People's Commissars directed the Academy of Sciences to solve, as an "important and urgent" problem, the "correct distribution of industry in the country and the best rational use of its economic forces".

Accordingly while tracing the source of Soviet science from its early days to the present work-force of 1.3 million scientists ("the largest scientific team in the world—its potentials are enormous") Aleksandrov found it necessary to devote almost a sixth of the article to the Cold-War.

Partly, it is clear, he wanted to exculpate Soviet scientists involved in armaments production.

Then, after a brief paragraph on Brezhnev's peace initiatives, Aleksandrov moved the attack to the economic front. The Soviet Union "carrying out Lenin's directives has created a reliable fuel-energy basis of its own, a diverse basis of raw materials, and all forms of industry. . . . "There is no scientific-technical problem" he concludes triumphantly "that would not be within our power".

Imports of such technological goods as gas pipelines, he explains, are simply a way of receiving payment for exports of "excess production", and allow "advances in the necessary sectors" to be made; they are never, he averred, "vitally necessary".

To ram his point home, he then described the US economy, on the brink of energy shortages and major economic crisis, following this by a review of the benefits of Soviet science, "not only for our country, but for mankind as a whole"—the first nuclear power station, the first nuclear ice-breaker, the start of space research. Other Soviet successes, he maintained, had "given the impetus for corresponding work to be done in the West"—lasers, Cerenkov radiation, "certain principles of thermonuclear synthesis", and "the production of relativistic electrons".

The final column is quieter in tone; an allusion is made to Mr Brezhnev's enthusiasm for basic research, the instrument-construction and computer sectors receive a slight censure, the RATAN-600 telescope and Baksansk neutrino observatory are particularly praised.

And that is all. The feast-day of Soviet science, as portrayed by Aleksandrov, is an entirely Soviet celebration. The outside world is cited only to make the Soviet picture shine more brightly by contrast.

Perhaps most significant, although the politicians regularly mention scientific and technical cooperation as one of the benefits of the Helsinki accords, Aleksandrov does not reciprocate the compliment. In what must, by its length and occasion, count as a major statement on Soviet science policy, the word "detente" is never mentioned.

. . . but bring the Bulgarians down with a bump

ABORTING the Soyuz-33 flight with the Soviet and Bulgarian cosmonauts must have proved particularly embarrassing to the Soviet space planners. Not only was it a premature return, but it took place on "Cosmonautics Day" (12 April, the anniversary of Gagarin's flight).

Bulgaria's space research programme has always been particularly closely linked to that of the Soviet Union. It was initiated in 1956 following a Soviet suggestion that the Bulgarians should explore the possibilities of carrying out ionospheric research and monitoring future Soviet satellites. The Bulgarian Council of Ministers established a Centre for Radio-Observation and Ionospheric Research, which was ready to go into operation when Sputnik-I was launched in October 1957.

At the same time, other Comecon countries—Czechoslovakia, Poland, East Germany and Hungary, were making a firm commitment to space research. This, however, was a stepping

up of existing efforts, not, as in Bulgaria's case, an entirely new initiative.

By 1966, when the *Interkosmos* programme was initiated, Bulgaria had caught up considerably. From the beginning, there was a major Bulgarian participation in the *Interkosmos* working groups on space physics, satellite communications, space meteorology and space biology. On the hardware side, Bulgaria was still somewhat behind although *Interkosmos-2* included a joint Soviet-Bulgarian Langmuir probe experiment. By December, 1972, Bulgaria was able to provide a complete experiment, monitoring electronic and ionic concentrations and temperatures. Updated versions were later carried by the *Interkosmos-12* and -14 satellites, and the *Vertikal-4* and -5 geophysical rockets.

In addition, Bulgarian scientists have been involved in the equipping and processing of experiments carried by several Soviet *Kosmos* satellites. Throughout, Bulgaria's main interest has been directed towards particle and field distribution, including some interesting results on magnetosphere shock-waves. It is to such experiments that Bulgaria's own satellite, *Bulgaria-1300*, will largely be devoted.

This satellite is intended to celebrate the forthcoming 1300th anniversary of Bulgarian statehood, and will presumably engage the entire launch power of an *Interkosmos* blast-off, resembling the Polish *Copernicus-500* jubilee satellite of 1973, rather than the small Czechoslovak *Magion* satellite, which was put into orbit as part of *Interkosmos-18* last autumn.

Bulgaria would then become the second non-Soviet Comecon country to have a satellite of its own—which should compensate considerably for the loss of *amour-propre* over the *Soyuz-33* abort. Indeed, the Bulgarian media have already done an excellent PR job on *Soyuz-33*—backed up by the Soviet and Bulgarian governments which have awarded Ivanov and his Russian commander Rekavishnikov the usual orders and titles. The return to Earth, using the back-up engine for re-entry, and the reactions of the cosmonauts to this "short but difficult" flight were presented as valuable lessons in space dynamics and psychology.

As for the Bulgarian experiments designed for the mission—which were to include a unique spectroscopic survey of the Earth—these will almost certainly be carried out by a repeat mission in the near future. So, when the current programme of *Interkosmos* manned flights comes to an end, Bulgaria may well have two manned flights (and possibly two cosmonauts) to her credit, while the other fraternal allies have only one apiece.

Ivanov: awarded the usual medals

Vera Rich

Union steps up lab safety campaign

UNION action at UK university and public health laboratories which use dangerous pathogens is to be stepped up in further attempts to improve safety. The Association of Scientific Technical and Managerial Staffs (ASTMS) has warned that it is now to launch a campaign to enforce greater safety at laboratories dealing with category B pathogens—such as those responsible for botulism, typhoid, paratyphoid and the plague. These are organisms less deadly than the category A smallpox virus which caused the death of medical photographer Janet Parker at Birmingham University last year but they still pose special hazards for workers.

The general secretary of ASTMS, Mr Clive Jenkins, said last week that the union would be telling its members: "Do it cleanly. Do it safely. Wear masks when necessary. Use the autoclaves. Use the fume cupboards. Demand things be made safe from the beginning". And he added: "We still have a situation in about 60% of our laboratories where mouth-pipetting is still permitted. That is disgraceful, awful. We will certainly be urging our members to stop mouth-pipetting at these category B laboratories."

"I think heads of departments are being dirty, careless and slovenly. There is no excuse for doing things incompetently, inefficiently and in a dirty fashion".

Mr Jenkins said the Birmingham smallpox outbreak and the subsequent revelations of the Shooter report had spurred ASTMS to take a fresh look at the 29,000 people in the laboratory population of universities and the health service. "These people are being ravaged by disease and are contracting all sorts of things like brucellosis, psittacosis, beryllium contamination, TB, hepatitis, and about eight or nine other things as well", he added.

The union now has 2,000 legal cases pending on behalf of its members—of which about 60% are related to diseases with industrial or laboratory sources. More staff have been taken on to help cope with this load and ASTMS has also rejigged its entire legal department to be investigative rather than retaliatory, Mr Jenkins added. "Our members are flooding us with calls now they realise that we are passionately interested in this area", he claimed.

ASTMS is now negotiating a new pay package for its technicians and is expecting a 9% rise backdated to last

Clive Jenkins: mouth pipetting "is disgraceful"

October which is to be followed by three other increases over the next 18 months. But Mr Jenkins stressed that although this claim had led to several disputes at departments, the union was trying to rein in its members. "One can damage a university without having any effect at all upon politicians or upon the economy and therefore we feel guilty because in the private sector we have been getting quite sensible agreements. But the universities are a real problem for us".

"We want to abolish the concept of danger money", Mr Jenkins said. "The arguments that we would use are that this is a very hard-working, productive, active and well-qualified group. Discussions about disease are separate. University technicians should be properly rewarded for their qualifications and work but we are not going to be bought off for more money to have them working in slovenly laboratories".

At the same time, ASTMS is still pressing for a public inquiry into the Birmingham outbreak with a legally qualified chairman and some form of union representation. Indeed this latter approach is a particularly important one for the union which wants far greater union representation on all bodies administering laboratories.

And Mr Jenkins reacted bitterly to the suggestion reported in *Nature* (29 March, p. 387) of Mark Carlisle, Conservative education and science spokesman, that there should be no lay or union members on the Dangerous Pathogens Advisory Group, the body responsible for screening biological laboratories such as the one at Birmingham.

"I would have thought that that was a scandalously reactionary suggestion. DPAG has been a disaster. We want it disbanded. Everyone inside it should be sacked and the body reconstituted within the Health and Safety Executive. I don't know why he wants the Tories to be the party of germs and danger".

Robin McKie

UK taxonomy is healthy, says report

A REVIEW group of the UK Advisory Board for the Research Councils (ABRC) has recommended that the major support in Britain for taxonomy—the classification of plants and animals—should go to studies of organisms of economic and social importance. Most in need of study it says, are the nematodes, tiny and prolific worms that attack crops and livestock throughout the world. This reflects the concern of the European Science Foundation Group on Biological Recording, Systematics and Taxonomy, which in 1977 instituted a survey of European plant-parasitic nematodes.

The classification of plants and animals may not be one of the more glamorous branches of biology, but the accurate identification of species, both past and present, and the study of their relationships is basic to both fundamental and applied biological progress. Reawakened interest in the field has inspired the official ABRC report, *Taxonomy in Britain* (HMSO, £3.50). The report has been produced by the ABRC's Review Group on Taxonomy, set up in 1974 under the chairmanship of Sir Eric Smith, formerly director of the Laboratory of the Marine Biological Association of the United Kingdom.

The state of British taxonomy seems on the whole to be healthy, the report concludes, although the group would like to see some changes, particularly to ensure proper care and use of the scattered national collections of biological specimens, and to encourage young people to take up taxonomy.

Also, the British collections of living material including, as well as the plants in the botanic gardens, cultures of algae, protozoa, yeast, bacteria, fungi and viruses, have special needs not shared by dried specimens. The report expresses particular concern about uncertainties in the funding of the collection of living fungi at the Commonwealth Mycological Institute and of the National Collection of Yeast Cultures and recommends that the ABRC review the funding of all such taxonomic reference collections.

To encourage recruitment and training of taxonomists, the report recommends that the study of taxonomy should be fostered as part of the general educational exposure to science and natural history. Field courses are vital, says the report. To build on these foundations there should be a modest increase in the small number of post-graduate studentships for taxonomic research.

Mary Lindley

Planners backtrack after German nuclear inquiry

Most of the plans for a reprocessing plant at Gorleben are only drafts after all. **Klaus Höpfner** reports on surprise developments at the hearing into West Germany's 'Windscale'

DURING the last big debate on nuclear energy in the West German Bundestag in December 1978, speakers described the present situation over the country's atomic waste as "precarious" and "critical". They placed their hopes in the swift completion of the central nuclear disposal centre at Gorleben in Lower Saxony.

Since then, the storage ponds for burnt-out fuel elements in the German nuclear power stations have filled up still more, the construction of a larger intermediate storage facility at Ahaus in North Rhine-Westphalia has been further delayed, and there are still problems with the temporary dumping of used fuel elements at La Hague in France.

Moreover, plans for the reprocessing and final disposal installations in Gorleben have run into trouble. Severe criticism has been made by 25 international scientists called in by the local *Land* government of Lower Saxony (the authority responsible for plant licensing) to assess the plans. Their 2,200-page report set down little that was encouraging for the pro-nuclear lobby.

During a six-day hearing in Hanover from 28 March to 3 April, these expert critics argued with the Gorleben planners and also explained the plans to a wider public. Initial fears that the press and public would be excluded and denied sensitive information were not borne out. Although the scientists' report has not yet been published, notes of the sessions were distributed and the hearing was open to detailed reporting by the media. Neither has there been any substance so far in the fear that the hearing would merely be a front, and that it would have no influence at all on the decision whether or not to build the plant. On the contrary it seems as if doubts raised about safety and the incompleteness of the existing plans have already begun to have an effect. The Minister-President of Lower Saxony, Ernst Albrecht, made it known, while the hearings were still going on, that the project in its present form would not get his government's approval and would have to be altered. DWK, the German nuclear fuel reprocessing company which is designing and building Gorleben, reacted by declaring that, contrary to all assumptions, large portions of its plans were only preliminary and open to alteration. Only the first phase of construction—the entry storage ponds of

the plant—was decided and needed to be licensed now. Plans for the other phases—reprocessing plant, uranium and plutonium fabrication, vitrification of wastes and final processing—were simply drafts (which nevertheless enabled a decision in principle on technical safety to be made).

The pro-nuclear case at the Hanover hearing was put by representatives from the industrial interests concerned, from nuclear research institutes and other scientific establishments in Germany and elsewhere. On the first day of the hearing, they described the plan as an "optimal draft", for which no alternative existed in the present state of technology. For safety reasons, a fully integrated disposal centre was the best solution. Transport of dangerous loads would be minimised, control of fissionable materials would be made easier, and the costs of guarding and protecting it from attack would be kept relatively small.

Of the three methods for the treatment of used fuel elements which were feasible in principle—namely: reprocessing, long-term intermediate storage with a view to possible reprocessing later on, and final storage in specially built facilities, the decision had been made in favour of reprocessing. This was on ecological grounds (reduction of dangerous materials to a minimum by treatment and re-use as reactor fuel) and on economic grounds (recycling, sparing of scarce uranium resources). Moreover, according to DWK, there was "no technically proven process that would permit highly burnt-out fuel elements to be stored safely over very long periods". Linnemann (Radiation Management Corp., Philadelphia) said it was a "logical, progressive and necessary programme" that would be recognised by many countries and by the International Atomic Energy Agency.

However, the battle over reprocessing must be seen in the context of the commercial use of breeder technology which the German electricity industry is striving for. This is meeting strenuous opposition, as much from the political parties (whose leaders are still leaving the decision open) as from the environmentalists and pressure groups which have achieved considerable success lately at local elections.

Technically, reprocessing is to be by the PUREX process, which, says DWK, "has held good for over 30 years in a large number of treatment plants",

including a small experimental plant in Karlsruhe. Even its advocates admit that the PUREX process, which was developed in the 1940s for military nuclear programmes, still has important technical problems to overcome with the much higher radioactivity of the fuel elements from power reactors (especially in the first stages of the reprocessing, when dealing with the radioactive gases given off). They also concede that many of the steps in the process still have to be adapted for the major technical requirements of a plant with a capacity of 1,500 tonnes a year. Nevertheless, the pro-nuclear supporters in Hanover appeared firmly convinced that all the problems could be solved, and spoke of "normal steps" such as are usual with every advance in technical development.

The general question of the expediency and safety of reprocessing plants, and the technical problem of how far experience with small reprocessing plants can be applied to plants many times bigger became increasingly important during the hearings. The sharpest critics flatly denied that the large-scale reprocessing of reactor fuel elements would ever be feasible. Reprocessing made one problem (the final storage of used fuel elements) into a whole series of problems whose solutions "have never been successfully demonstrated on an industrial scale" according to Walt Patterson (London). It was ecologically senseless because it did not reduce radioactive waste, but increased it, and did so in an uneconomic way, with much higher costs than returns from the nuclear fuels recovered. Scarce uranium stocks could be eked out better in other ways, eg. in enrichment and in the production of the fuel elements. Professor Lindstrom (Stockholm) tried to quantify the dangers: the problems of reprocessing were "more difficult to the order of magnitude of seven" than those of designing a nuclear reactor, and the risks were correspondingly greater. Mr Schapira (Institut Physique Nucléaire, Orsay), supported this with a long list of only the "most important unsolved problems".

Amory Lovins (London), Professor Barnaby (Stockholm) and others saw the greatest problem in the 14 tonnes of plutonium which would be obtained in the plant each year and would have to be guarded against misuse. The huge capacity of the plant could possibly also be used to treat nuclear fuels for countries which were not a party to the agreement limiting atomic weapons and, in practical terms, to start an export trade in plutonium.

Ghostly garb for anti-nuclear demonstrators in Hanover

Minister-President Albrecht disagreed with the critics on this. The federal government kept strictly to the terms of the non-proliferation treaty. In any case, the treaty ought not to lead to discrimination against countries with no nuclear weapons by denying them access to a closed nuclear fuel cycle—that is, to reprocessing and production of plutonium fuel. From the designers' side, it was added that the plant would not have any extra capacity. That would be to assume that—after clearing up the stocks of atomic waste—there would eventually be 50 nuclear power stations in West Germany. At present there are only 12 (excluding experimental plants) and resistance is growing with every licence that is granted.

Serious misgivings were also raised during the hearings about the safety of the planned entry storage facility, which has been conceived as a "wet store" (water pools in massive concrete structures). A number of scientists warned of the catastrophic consequences of a breakdown in the coolant supply. To this, astonishingly, the designers conceded that the draft, commissioned in 1977, was in fact out of date. They were now thinking of dry storage in metal containers in which the fuel elements would lose heat naturally to the surrounding air (similarly to when they are transported).

Another controversy was about the best way of treating highly active wastes (more than 1,000 cubic metres of concentrated highly active solutions per year), and final storage in the salt domes of Gorleben or in other places with a similar geological formation. Three variants of highly active waste vitrification have been developed in Germany. It is now a question of putting one of them into practice.

For the final storage of radioactive wastes, the *Land* government of Lower Saxony chose the salt dome at Gorleben, near the East German border. But, geologists at Hanover said the geological conditions there were by no means the best. There were sure to be carnallite deposits there and probably anhydrite layers. In storing highly active wastes, special problems would have to be anticipated because of their heat radiation. Building a disposal centre on top of the salt dome would add to the hazard.

Immediately after the six-day hearing, which evoked great public response, particularly in light of the events at Harrisburg, it was clear that there was no basis, either scientifically or politically, for a comprehensive decision in principle.

DWK is now trying to exclude from discussion, for the time being, the most explosive part of the draft—the reprocessing plant. They argue that there is no pressure of time about the reprocessing; that it is not expected before the beginning of the 1990s, and breeder reactors are indeed a matter for the

21st century. There is no hurry either, they say, for the final storage facility, which is scheduled for 1995. Only the further steps for licensing the entry storage facility need to be hurried. Even this, though, should not be too pressing because the major intermediate storage facility at Ahaus should be ready before then.

Meanwhile, there is speculation that Minister-President Albrecht will reduce the decision to one small first step—further investigations into the entry storage facility—and for the rest avoid any commitment on future action. Not only would this gain time to test the feasibility of the plans, but alternatives could be more fully investigated. This applies principally to the option of long-term underground storage with the possibility of retrieval, which has been gaining more and more supporters. In theory at least, this has two advantages: it solves the problem for today and keeps the options open for the future. Its disadvantage is that there has been hardly any experience with it.

Minister-President Albrecht could find himself in a political dilemma in making his decision. He is a member of the executive committee of a political party (the CDU) which is still in favour of nuclear energy. At the same time, Gorleben is anything but popular, and Albrecht governs Lower Saxony with only a bare majority. His opposite number, the former Federal Minister of Building, Ravens (SPD), is only waiting for one wrong move. So Albrecht has now sought an interview with federal Chancellor Schmidt. Without powerful backing from Bonn (where federal Research Minister Hauff has already mounted a big information operation to take the disposal plan to the people), he will be reluctant to give the go-ahead. Since Harrisburg, though, Bonn is even more divided over the nuclear energy question than before. □

Klaus Höpfner is a writer with the Institut für Systemtechnik und Innovationsforschung, Karlsruhe.

'Splash-over' caused Windscale leak

FIGURES on the Windscale leak discovered by borehole sampling (29 March) have finally been released by British Nuclear Fuels. A spokesman said preliminary estimates of the total activity in the leak are from 10,000 to 100,000 curies, the total volume of escaped radioactive liquid is 200 gallons, and the dosage in the borehole is 300 rems per hour. (The International Commission on Radiological Protection calls a dosage of 400 rems lethal.

The leak has been located in an out-

of-use storage site for waste analysis where active liquid from the processing chain was diverted into unused piping to the storage shed due to a "splash-over at a junction point". The maximum activity is 15 to 20 feet under ground and is separated from ground water by a layer of clay. The route of the leak from the storage shed to the borehole is unknown.

BNFL has told police, fire, health service and county council official that there is no hazard to the community or the workforce. □

DPAG needs public interest representatives

SIR.—I refer to your article (29 March, page 387) "Britain's shadow science minister believes in experts."

If the substance of your article really does represent the views of Mr Carlisle, perhaps the headline would have more accurately read "believes in non-trade union experts" or even "anti-trade union experts."

The plain fact of the matter is that the Dangerous Pathogens Advisory Group (DPAG), which does not have representatives from the trade unions or from the community, and consists solely of experts in the sense that the Conservative shadow minister uses the word, has in safety terms been a disaster. GMAG, which does include representatives of the public and trade unions, has been able to exercise a positive, constructive and effective role in the area in which it operates. The comparison is dramatic.

Of twelve laboratories cleared by the non-statutory "leave it to the experts" DPAG (which excludes trade union representatives) as safe to handle Category A pathogens, the Health and Safety Executive has now served prohibition/improvement notices on three. No such problems have arisen in laboratories working in the field of genetic manipulation experimentation! These have been controlled from the outset by close cooperation between the Health and Safety Executive and the Genetic Manipulation Advisory Group which does, of course, include the Trades' Union Congress (TUC) nominees and representatives of the community. This is because trade unions' organising staff doing such work can provide experts as good as any, with the added advantage of links with democratic organisations possessing economic and political clout. This makes it possible to defend the interests of the public and employees to a degree DPAG has either been unwilling or unable to do. The consequences have been tragic as we well know from the smallpox occurrence at Birmingham, and the laboratory now closed as unsafe was cleared by a DPAG system. Mr Carlisle evidently holds in such high regard

Would it be fair to conclude that Mr Carlisle is moved by fossilised Conservative policies, rather than the health and safety of the community and of the work people concerned.

Yours faithfully,

R. A. BIRD

Association of Scientific, Technical and Managerial Staffs,
London

International energy programmes need coordinating

SIR.—In the face of the approaching threat of a world energy shortage Professor Rotblat's "Call for world

(non-nuclear) energy organisations" (1 March, page 4), to coordinate and stimulate the development of non-nuclear sources of energy seems a positive step. But will this include oil, natural gas and coal? If Professor Rotblat is referring only to the so-called renewable energy sources any means of increasing their contribution beyond the 2% of world energy supply by the year 2000 suggested in a recent report to the Club of Rome deserves encouragement.

Something is, however, already being done. the World Bank Group has lent \$10 billion since 1948 for building power plants. In 1978 alone it lent \$1,146 million for energy and power projects in developing countries—all non-nuclear (almost 20 times the 1978 budget of the IAEA). Furthermore the Centre for Natural Resources, Energy and Transport at the United Nations, as well as the UN Regional Commissions, actively promote all non-nuclear forms of energy, as do UNESCO, UNIDO and UNEP and the US/AID. What is needed is a greater concentration and coordination of the programmes of existing agencies—not a new one.

If the world is to avoid a damaging energy crisis with widespread unemployment, protectionism and even armed conflict over limited energy supplies, all available energy sources—including nuclear power—must be developed, and energy conservation programmes increased. Professor Rotblat is then misguided in attacking what he calls the "promotional" activities of the International Atomic Energy Agency.

In fact a major role of the IAEA is in developing an institutional regime within which nuclear power can be used safely and securely. IAEA's 1979 'assessed' budget provides approximately \$20 million for regulatory activities (of which \$15.6 million are for safeguards against proliferation) compared with \$3.4 million for the division that deals with nuclear power and reactors.

The other promotional activities of the IAEA are in subjects like theoretical physics and fusion or for application of radio-isotopes in biology, medicine, food and agriculture. They are designed to help the great majority of the developing countries for which nuclear power is hardly, if at all, in prospect.

In addition to the "assessed" budget there is a voluntary technical assistance budget. In 1977, 21.9% of this went to nuclear engineering and technology (chiefly training in the safe operation of nuclear plants) compared with about 40% for application of isotopes in agriculture, hydrology, medicine, etc.

Professor Rotblat's main contention that a large expansion of nuclear power would greatly increase the chance of nuclear war, since almost every nation would have access to plutonium, flies in the face of the facts of history, economics and technological development. All nuclear weapon programmes have been based on series of special facilities dedicated solely to

military purposes and quite independent of the civil power programmes of the countries concerned. This separation becomes even more marked as time goes on. It is far cheaper, easier and less conspicuous to build and operate the small purpose-built plants needed for a modest weapon programme than to engage in commercial nuclear power. The difference in cost is of the order of twenty to one. Stopping nuclear power would not cause a moment's pause in the nuclear armament and submarine programmes of the weapon states.

A more immediate threat to world peace comes from competition over limited supplies of oil. According to a report in the *Financial Times*, 26 February, 1979, the US Defence Secretary has said that in protection of vital Middle East oil supplies "we will take any action that is appropriate, including military force". By increasing energy supplies and reducing the pressure of demand over scarce resources nuclear power will prove to be a stabilising factor in international affairs.

Professor Rotblat may not think much of treaties and international safeguards, but the fact is that the rate of proliferation of nuclear weapons has declined each decade since 1944. At the same time almost all the industrial and many of the leading developing countries of the world have benefitted from the peaceful use of nuclear technology. The danger of nuclear war comes from the arsenals of the great powers and not the power plants of the small.

Yours faithfully,

G. GREENHALGH

London, SW15.

Recombinant DNA dangers and wild *E. coli*

SIR.—Many scientists engaged in recombinant DNA research now expound the doctrine, referred to by Eleanor Lawrence in her report on the COGENE meeting at Wye (12 April, page 590), that the dangers that might arise during the course of their experiments cannot be greater than the dangers posed by working with the most dangerous organisms employed in those experiments. This might well be so when the recipients of genetic material are 'enfeebled' organisms such as *E. coli* K12, but it could be far from true if other recipients were employed, deliberately or accidentally. For example, to my mind, the implantation of efficiently expressible genes for botulinum toxin production in wild *E. coli* or other organisms that can multiply relatively freely in the food or in the intestinal tract of man or animals represents a much greater danger than the presence of these genes in *Clostridium botulinum* itself.

Yours faithfully,

H. WILLIAMS SMITH

A pioneer's view of Venus

from Garry E. Hunt

VENUS, our nearest planetary neighbour, has long been thought to be the Earth's sister, because of its similarity in size and mass. But the rapidly advancing knowledge of Venus gained from Earth-based telescope studies, and the measurements taken during space missions, has shown that the planets are actually quite different. Without doubt, the most dramatic development in our understanding of Venus, and one that has also changed our theories of how the Solar System was formed, has come from the recent Pioneer multiprobe orbiter mission, whose initial results were described recently in *Science* (203, 743; 1979). (Except where stated all following references are to that issue).

Descending through the thick atmosphere, the neutral mass spectrometer (Hoffman *et al.*) and the gas chromatograph (Oyama *et al.*) showed surprisingly large concentrations of ^{36}Ar , ^{38}Ar and ^{20}Ne . The volume mixing ratio of ^{36}Ar in the Venusian atmosphere is approximately 90 times greater than that of the Earth's. It follows that the absolute abundance of ^{36}Ar in the Venusian atmosphere must be approximately 200 to 300 times larger than the Earth's. The abundance of ^{20}Ne is also higher in the Venusian atmosphere and comparable to that of ^{36}Ar . The ratio $^{36}\text{Ar}/^{38}\text{Ar}$ is similar to values observed for the Earth, meteorites and the Moon.

The ^{36}Ar measurements have a profound effect on theories of the formation of the Solar System. Taking the Viking measurements for Mars into account (see for example Anders & Owen *Science* 198, 453; 1977) we now find that the amount of argon decreases from Venus to Mars. This suggests that the solar nebula, out of which the planets were formed, had an inhomogeneous distribution of material. The inert gases, such as argon, were trapped in the grains which formed the planets and settled as a veneer on these bodies as they condensed out of the nebula. These discoveries by Pioneer Venus have clearly reshaped our thinking on this important

subject. To obtain a more detailed picture we need similar measurements of other Solar System objects, and in the foreseeable future the probe measurements of Jupiter and the studies of cometary atmospheres could yield invaluable data.

The multiprobe system on the Pioneer spacecraft consisted of a bus transporting a large probe and three small probes designed to land at a northern latitude, on the day side and night side of the planet. In this way a global picture may be developed from this set of measurements. The contrast of the atmospheric structure below an altitude of 50 km at the widely differing locations was found by Seiff *et al.* to be no more than a few degrees Kelvin, with slightly warmer temperatures at 30°S than at 5° or 60°N . The atmosphere was stably stratified above 15–20 km, suggesting that near adiabatic lapse rate is maintained by the atmospheric motions. The profiles move from near adiabatic toward radiative equilibrium, at altitudes above 40 km. There seems to be a region of vertical convection above the dense cloud deck, in the altitude range of 47.9 to 49 km, where the temperature is approximately 360 K.

Venus is covered with a ubiquitous layer(s) of cloud, whose structure is intimately associated with the observed temperature structures. From their orbiter measurements, Travis *et al.* have detected a substantial layer of sub-micron particles of thickness 0.05–0.1 in the lower stratosphere, well above the main sulphuric acid haze layer. Stewart *et al.* find evidence of albedo features at 2068 Å which corresponds to the bright and dark features seen in the Mariner 10 images. The dark regions may therefore be locations where SO_2 is strongly absorbing. Taylor *et al.* find temperature contrasts of 50 K between a cold circumpolar band. Beneath these visible clouds, the layers of material have now been examined in detail by the Pioneer instruments.

A middle cloud region exists between 51 and 56 km and shows a decrease in concentration to about 100 cm^{-3} according to Knollenberg and Hunter. This layer appears to contain both liquid particles and solid grains of

radius 10–20 μm . The dense layer lies between 49 and 52 km with the visibility restricted to less than 1 km. This is the region of largest particle size observed. Just beneath this thick layer is a distinct thin layer of somewhat reduced opacity.

The region from 32 to 48 km below these clouds possesses a thin haze of particles nearly $1\text{ }\mu\text{m}$ in size with concentrations of 1 to 20 cm^{-3} . The upper part from 47–49 km is most dense and corresponds to the region of convective activity observed by Seiff *et al.* Below the lower boundary the atmosphere appears to be free of particles all the way to the surface. However, this does not mean that the visibility is unlimited. The Venusian atmosphere is so dense that the scattering of light by gas molecules alone will hide the surface from view.

The general behaviour of the measurements reported by Knollenberg and Hunter, and Ragert and Blamont indicate a concentration of particle independent of height or decreasing at lower altitudes. This behaviour is consistent with a source at the top and sink at the bottom, and a downward flow by mixing and by gravitational settling. This suggests there is a source of sulphur and H_2SO_4 at or about 57 km, which is the top of the middle cloud region. The source is presumably photochemical in nature, requiring ultraviolet radiation that does not penetrate far into the sulphur cloud. The H_2SO_4 droplets lose water on the way down, but they encounter increased H_2O and perhaps SO_2 and SO_3 to form the lower cloud region of dilute acid and the densest layer. Most important, the large particle size ($>10\text{ }\mu\text{m}$) encourage the possibility of precipitation on Venus either in the dilute H_2SO_4 lower cloud region, or initiated by sulphur from the middle cloud region, which would pick up dilute H_2SO_4 when falling below 51 km.

Several substances, besides water, are almost nonexistent above the clouds but well represented below them. The abundance of SO_2 varies in this way by a factor of 240 and oxygen by 61 (Oyama *et al.*). These higher abundances arise when sulphuric acid and sulphur rain out of the clouds, vapour

ise and even dissociate in the heat below and then chemically attack gases found in the lower atmosphere.

The presence of SO_2 and not COS (Prinn *Science* **182**, 1132; 1977) as the major sulphur-bearing compound in the lower atmosphere, is a great surprise. (Oyama *et al.*). Previously it was thought that the abundance of COS indicated that the amount of CO in the atmosphere is buffered by certain minerals at the surface, and its value is representative of the amount below the clouds (Lewis *Earth. Planet. Sci. Lett.* **10**, 73; 1973). Now these new measurements suggest that the CO (approximately 50 p.p.m.) is generated almost entirely by photochemical processes and that no significant amounts of COS should be expected.

The Pioneer measurements confirmed the surface temperature at $\sim 737\text{ K}$ and reasonably uniform, at the base of this huge CO_2 atmosphere. Since Venus and the Earth are nearly planetary twins, why are their atmospheres so different? This is not simply an academic question. The planets would have had some basic similarities in their initial state and the processes that have transformed Venus into its current inhospitable state might still occur on Earth.

Venus is much nearer the Sun and receives twice the incident sunlight that reaches the Earth. The additional heat would have quickly produced an efficient 'greenhouse' effect, increasing the atmospheric CO_2 opacity and raising the surface temperature to a level which would be too hot for any water vapour to condense into oceans. It is therefore important that we fully understand the evolutionary process of Venus to gain a better perspective of the possible perturbations that may affect the Earth's atmosphere.

Now, Tomosko *et al.* have found that only 2% of the incident sunlight reaches the surface. However, for the greenhouse effect to be maintained, Bolse *et al.* find that the contribution from the water vapour, whose mixing ratio is only 10^{-3} , is essential to provide the additional opacity which combines with the contributions from CO_2 and the cloud particles.

What is the origin of the present-day Venusian atmosphere? Observations of the surface of the planet are essential to address this problem, but this is obviously difficult because of the extensive cloud layers. Radar maps of the surface are being produced from measurements made from the orbiter (Pettengill *et al.*). Although the measurements are restricted to the region bounded by 74°N and 63°S , the high resolution observations show evidence of a rift valley having vertical relief of up to 7 km. There is almost the suggestion of volcanic features, which may indeed be responsible for the creation of the

current atmosphere. The surface of Venus may therefore have some similarities with other terrestrial planets.

One of the most startling observations was made as the spacecraft descended toward the surface, where in the altitude range of 6–14 km, lightning storms were encountered. At least 1,000 impulses of radio noise were measured. Lightning on Venus is not unreasonable, since the atmosphere is electrically active. By way of comparison, there are typically 100 lightning strokes every second scattered all over the Earth. But on Venus there may be several times that number in a localised area. Instead of being illuminated for a brief instant by a dazzling flash of lightning, as on Earth, the Venusians may well be glowing from the nearly continuous discharges of those frequent lightning strokes. We have also gained a bonus measurement from the day probe which unexpectedly survived on the surface for more than an hour. It impacted on a surface composed of loosely compacted material so that a small amount of fine dust was ejected from the surface into the atmosphere in the vicinity of the probe (Ragen & Blamont). The dust subsequently settled out on to the surface in a few minutes.

The orbiting spacecraft travels on an eccentric path with a periapsis altitude of $\sim 200\text{ km}$ and apoapsis of $\sim 67,000\text{ km}$, and carries a range of instruments to investigate the properties of the upper atmosphere. Taylor *et al.* find that in the 60–140 km region of the atmosphere, there are small diurnal temperature differences near the cloud tops which increase with altitude. The pole-to-equator tempera-

ture contrasts are much larger. An isothermal layer of at least two scale heights in the vertical is found near the 100-kilometre altitude, where the temperature is $\sim 175\text{ K}$. The monitoring of this region above and in the neighbourhood of the cloud top is important in determining the mechanisms of the meteorology of this region.

In spite of the absence of any appreciable magnetic field, the ionosphere of Venus seems to repel the solar wind at least as well as the terrestrial magnetosphere (Wolfe *et al.*; Scarf *et al.*). At Venus, streams of particles and radiation from the Sun confine the ionosphere below a well defined boundary. This is called the ionopause, and is not found around the Earth. One of the major surprises is the presence of the ionosphere on the night side of Venus. The ions and electrons that produce this region should recombine when the Sun is removed as an excitation source. On Venus, the night lasts for 8 weeks, so it was at first thought that the ionosphere should disappear (Taylor *et al.*). Perhaps the atmosphere at these levels rotates more rapidly than the planet and therefore prevents the charged particles from neutralising.

The Pioneer Venus mission, with the orbiter and sophisticated probe systems has provided a great deal of information on our nearest neighbour. The *in situ* measurements of the atmosphere have produced surprising information that has changed our understanding of the formation of the Solar System. This is an amazing accomplishment. Detailed exploration of the planets always yields surprises and gives a new perspective on the Earth. □

Nerves, molecules and embryos

by Miranda Robertson

THE interactions of nerve cells with one another and with their environment at any stage are incompletely understood; the least understood of all are those that take place during embryonic development. Two philosophies can be discerned among biologists in this difficult field. One is that developing animals are so complicated that experiments on them cannot possibly yield interpretable information on the molecular mechanisms underlying development, and the only reasonable strategy is to investigate selected developing cells *in vitro*. The other is that because development is so complex

and the topology of the developing animal so important, nothing interesting can be learned about its mechanisms from cells, or even tissues, in culture.

They are probably both right; and a recent meeting* largely devoted to neural interactions in development therefore started propitiously with a talk from N.M. Le Douarin (CNRS Nogent-sur-Marne) whose work on neurochemical differentiation in chicks has recently run in reassuring parallel with that of the Harvard group, represented at the meeting by L. Chun and D. Potter, on neurochemical differentiation in Petri dishes.

The issue is what determines whether a sympathetic ganglion cell will become noradrenergic or cholinergic. Le

*A meeting on Cell-Cell Interactions in Neurobiology was held on 12–15 February, in San Diego. It was partly sponsored by the National Foundation March of Dimes.

Douarin's contributions to this question are based on the use of tissue grafts from quail embryos into chick: the grafted cells participate in the embryonic development of the chick, where their progeny can be identified by a stable nucleolar marker peculiar to quail. By grafting small pieces of quail neural crest into more anterior or more posterior positions in chick neural crest, she has been able to show that the migration pattern of the cells to the sympathetic ganglia and other structures is determined by their position on the antero-posterior axis, their neurochemical differentiation probably being induced by tissues at their destination.

Investigations by the Harvard group have suggested that the inducing influence is a soluble factor released by the target organs of the neurones: adrenergic neurones dissociated from the superior cervical ganglion of the rat are induced to express cholinergic functions instead if they are cultured with (for example) heart cells, or medium in which heart cells have been growing ('conditioned medium'). The existence of soluble factors would imply that direct cell contact is not necessary, but there are indications from preliminary experiments by E. Hawrot on ganglion cells cocultured with dead heart tissue that a cell surface factor may also exist (L. Chun, Harvard University Medical School).

The discovery that ganglion cell neurochemistry can be manipulated in this way has raised the question of how stable the differentiation of neural crest cells is even after they have reached their destinations. This stimulated Le Douarin to show that a similar switch can be induced *in vivo* by transplanting cholinergic ganglion cells from 4-6-day quail embryos to a potentially adrenergic region in the neural crest of chick embryos at an earlier stage of development (Le Douarin *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 2030; 1978). It has yet to be established how late in development ganglion cell differentiation remains reversible, but there is now some evidence that activity induced by presynaptic fibres may be what stabilises transmitter choice. This was originally suggested by some experiments of Black *et al. (Brain Res.* **34**, 229; 1971), and the Harvard group has been able to show that depolarisation induced by various means can prevent the effects of conditioned medium on cultured ganglion cells (Walicke *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 5767; 1977). The importance of the soluble factor in conditioned medium is that it specifically induces differentiation, without affecting growth or survival (by contrast with nerve growth factor, for example, which enhances growth and survival without influencing

differentiation). It is therefore crucial to establish clearly that conditioned medium truly causes phenotypic switching and not merely the differential survival of cholinergic cells in an already heterogeneous population. The Harvard group now has persuasive evidence for switching, from the results of experiments in which one or at most two cervical ganglion neurones are grown on a bed of heart tissue with which they can synapse. By monitoring the effects on heart cell contraction of stimulating the individual neurones, they have been able to show that neurones which by all available criteria were adrenergic at the start, become dual function (presumably in the process of switching) or cholinergic in such culture conditions.

Soluble factors

One consequence of Petri-dish embryology is that developmental neurobiology is beginning seriously to rival immunology in the proliferation of uncharacterised or semi-characterised 'factors' which are identified by their important but ill-understood actions on cells *in vitro*. G. Fischbach (Harvard Medical School) has made a start on the characterisation of a factor from spinal cord explants which will induce within hours an increase in both the density and the clustering of acetylcholine receptors on cultured chick myotube. From its molecular weight and sensitivity to tryptic digestion, the factor seems to be a small peptide, possibly related to the activity reported by Podleski *et al. (Proc. natn. Acad. Sci. U.S.A.* **75**, 2035; 1978) in nerve extracts and which has similar effects on cultured rat muscle. Its relationship to those described by Anderson *et al. (J. Physiol. Lond.* **268**, 731 & 757; 1977) and Christian *et al. (Proc. natn. Acad. Sci. U.S.A.* **75**, 4011; 1978) from neural tube and neuroblastoma/glioma hybrids respectively is more problematical, since in both these cases there was receptor clustering without any significant increase in receptor density. The importance of factors influencing receptor distribution is that they may play a part in neuromuscular synaptogenesis. A recent controversy about whether the receptor clusters that form at the site of the synapse are intrinsic to the muscle or induced by the nerve has recently been settled in favour of the nerve (see *News & Views* **278**, 599; 1979); but the mechanism remains unknown.

Another factor was discussed by J. Brockes (California Institute of Technology), whose long-term aim is to find out what determines the interactions of

Schwann cells with the neurones the myelinate. Schwann cells can be induced to proliferate in culture either by agents which elevate intracellular cyclic AMP, or by a factor which is present in extracts of bovine pituitary and brain but which does not seem to be any of the more obvious hormone or growth factors, which have no effect on Schwann cell division. The factor is not found in non-neural tissue and is a basic protein of molecular weight about 50,000. While the signal that induces proliferation is thus partly characterised, the signal for myelination is so far detectable only operationally. Schwann cells distinguish between small-diameter axons, which they envelop without myelinating them, and larger ones around which they wrap their membrane to generate the myelin sheath. Brockes reported that Schwann cells make detectable amounts of the major peripheral myelin proteins only when stimulated to do so by contact with appropriate axons, and interact with artificial fibres in the way that they do with unmyelinated axons. This suggests that Schwann cells are induced to myelinate by a chemical signal from certain axons, rather than simply by the geometry of large-diameter fibres. Considerably more elusive than factors influencing differentiation have been those that influence morphogenesis; but it is increasingly believed that differential stickiness of cell surfaces may account for much specific contact-making, both between individual cells and between sheets of tissue. Dennis Bray (Washington University Medical School, St. Louis), investigating the general question of the mechanism of neurite outgrowth, presented results which may suggest how differential adhesion could direct the growth of nerve fibres. Growing neurites end in a specialised growth cone, from which filopodia extend symmetrically to attach to the substrate. By pulling the neurite gently to one side or the other, Bray has shown that the direction of growth follows the main axis of tension.

The importance of stickiness

So far, there has been no attempt to test theories of differential adhesiveness on actual embryos; but it became clear at the meeting that this could and should be done, specifically in the case of the adhesive molecule that G. M. Edelman and U. Rutishauser (Rockefeller University) have identified in cultures of chick retinal and tectal cells. It now seems possible that adhesive molecules on the surface of retinal cells may be the basis for the strict ordering of their connections with the optic tectum which it is now believed may be determined simply by the preservation of neighbour relations between

growing axons. This notion has recently been checked anatomically by J. Scholes (*Nature*, **278**, 620; 1979) against the optic nerve of Cichlid fish, which is ideal for such studies because it takes the form of a ribbon in which the radial coordinates of the retina can be shown by retrograde degeneration to map across its width, and the circumferential coordinates across its thickness. (Much the easiest way to envisage this geometry is to see the retina as a fully opened circular fan: close the fan and you have the beginning of a ribbon.) Scholes has established that neighbour relations are preserved with very little deviation for the whole length of the nerve almost up to the tectum, when discrete bundles of fibres (within which neighbour relations continue to be preserved) undergo a complex rearrangement before spreading out on the tectal surface.

Stickness, clearly, could explain this kind of ordering, particularly since the retina grows in successive rings from centre to periphery, and new axons could thus follow the adhesive surface of the neighbouring older axon. The work of the Rockefeller group on a cell adhesion molecule (CAM) in cultures of chick retinal and tectal cells (see *J. Cell Biol.* **79**, 371, 382; 1978) may provide a biochemical test for the nearest-neighbour hypothesis. They have used antibodies to CAM to disrupt such ordering as occurs in cultures of retinal cell aggregates and spinal ganglia in a way that suggests that CAM mediates the sorting out of cells and reunions to form tissue layers, and the antibody can inhibit the side-to-side adhesion between neurites that produces nerve bundles. It may thus be possible directly to test the nearest neighbour hypothesis by injecting anti-CAM into embryos during optic nerve development and looking to see if the retino-tectal map is scrambled.

While there is now some hope of discovering the molecular basis for short-range effects such as the induction of differentiation and the guidance of growing axons, the long-range or global control of morphogenesis remains as mysterious as ever. What, for example, causes the optic nerve fibres to undergo a systematic piecemeal rearrangement at the tectum (Scholes *op. cit.*)? Indeed, what in general determines the orientation of developing systems? This question was raised in J. Cooke's (National Institute for Medical Research, London) discussion of his recent work, which is concerned with the determination of orientation in the tadpole eye. If a tadpole's eye is rotated at any stage after the first few hours after spawning, the growing nerve fibres will turn before they reach the tectum and make the connections they would have made from a normal

eye, thus giving the frog a rotated visual map. According to some classical experiments by M. Jacobson (*Science* **155**, 1106; 1967; *Devl Biol.* **17**, 202; 1968), eyes rotated at earlier stages become respecified, making connections appropriate to the rotated eye and producing a normal visual map in the adult frog. Cooke has failed to repeat this finding and in the course of seeking the reasons for this failure he has touched on the kind of developmental phenomenon that is most resistant of all to molecular explanation.

Cooke and his colleagues never find normal maps from rotated tadpole eyes, no matter how early the rotation: they find either rotated maps, or compound maps in which half the visual field is rotated and half normal. By using albino tadpoles as the hosts and grafting rotated eyes from wild-type tadpoles, they have been able to establish from the histology that the compound maps are due to the partial regrowth of the host eye. They suspect that Jacobson's results may therefore have been due to the regeneration of normally oriented eye tissue, the absence of compound maps being due either to the death of the rotated tissue or to a gradual takeover by the regenerating tissue in the course of growth—since many of Jacobson's animals were mapped when relatively mature.

These experiments led Cooke to the question of whether in fact it is the rotation itself that induces the regeneration of host eye tissue. This question arises from the attempts of French *et al.* (*Science* **193**, 969; 1976) to explain the occasional duplication of regenerating structures. Their proposal which has become known as the 'clockface' model, is that growing structures are specified according to circular coordinates and that rotated structures can give rise to duplications at the site of the graft because of intercalary regeneration between discrepant clock-face values. To test whether rotation is thus causing the regenerative duplication of the retina in tadpoles, Cooke has experimented with grafts of unrotated eyes; and preliminary results suggest that in these animals regeneration does not occur.

This kind of interaction is particularly difficult to explain by any imaginable molecular mechanism. Not that any actual molecular mechanism has yet been found to account for the relatively approachable problem of Cartesian positional gradients, which are generally believed to account for most morphogenetic signalling. Scholes has pointed out that the retinal circular fan is a way of transforming circular to Cartesian coordinates. This may not help with the identification of a morphogenetic model; but it could point the way to a unified theory. □

Is DNA really a double helix?

from Struther Arnott

ALTHOUGH it is 26 years since the announcement of the base-paired double-helical structure for DNA, there are still attempts to answer questions about DNA without using the Watson-Crick paradigm. For example, Rodley *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **73**, 2959; 1976), Cyrax and G  th (*Naturwissenschaften* **65**, 106; 1978), and Sasisekharan *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 4092; 1978) have all proposed that the two strands of DNA do not coil plectonemically round one another. Thus, the problem of unwinding extensive lengths of cohelical DNA for replication is abolished at a stroke and new roles will have to be postulated for relaxase, gyrase, helicase and so on.

Rodley's structure is typical. It retains the antiparallel, complementary base-paired chains of the Watson-Crick structure and the 10-base pair axial repeat of B-DNA. Lack of mutual coiling is contrived by irregular chain conformations in which blocks of about five nucleotides have right- and left-handed twistings alternately. The resulting model is analogous to a warped zipper. Since the phosphate groups lie more or less on the surface of a cylinder with radius about 9 Å and the base-pairs are stacked 3.4 Å apart along the long axis of the molecule, it has many features in common with the double-helical model of B-DNA. The calculated diffraction pattern is therefore encouragingly similar to that observed from DNA fibres. Had such a model been available in 1953, it would have been regarded as a serious competitor for the original bihelical model.

Since 1953, the original DNA model has been substantially modified by Wilkin's school and refined to fit the >100 X-ray diffraction intensities which can be obtained from oriented and polycrystalline fibres of B-DNA. Recently, R. Chandrasekaran and I remeasured these intensities and re-refined the double-helical model of B-DNA which now provides a reliability index $R=0.28$, which is reasonable when one considers that fixed standard bond lengths and angles have been imposed on the model as well as specific base and furanose ring shapes leaving the six conformation angles of the generating nucleotide as the only variables. Poorer models have higher values for R . For example, a double-helical

Struther Arnott is a professor of biology and Head of Biological Sciences at Purdue University, West Lafayette, Indiana.

model with an unacceptable alternative base-pairing scheme has $R=0.45$. For the Rodley model $R=0.48$. These less regular warped zipper models have 10 times the degrees of freedom allowed to regular helices and would have to have $R<0.20$ to be regarded as being significantly superior to the best bihelical model according to Hamilton's test (*Acta Cryst.* **18**, 502; 1965).

It is not unthinkable to me that a warped zipper model could be contrived with R rather less than the present value of 0.48. The effort required would be considerable and, in the circumstances, one is inclined to look for more decisive experiments not requiring accurate knowledge of the atomic positions in DNA. Crick *et al.* (*J. molec. Biol.* **129**, 449; 1979) believe that studies of closed circular DNA molecules will suffice. When a closed circular DNA with N base pairs is unwound by known amounts, one can calculate the net number of times each chain is coiled round the other in relaxed DNA. This linkage number (α) turns out to be approximately $N/10$ as would be expected from the classical bihelical model rather than near zero as predicted for the warped zipper models. (By retaining a modest amount of coiling as a result of failing to balance exactly the right- and left-handed twistings, the proponents of the warped zipper structures have contrived that $\alpha \neq 0$ and avoided having to explain why closed circular DNA duplexes cannot be melted to give two separable classes of single-stranded circles.) Crick *et al.* argue also that the quantised migration of supercoiled DNA molecules in gel electrophoresis can arise only from the fact that all the molecules in one band have the same linkage number which differs by unity from that of molecules in adjacent bands, and that this can be explained only by assuming that the molecular secondary structure is double helical.

There is also crystallographic evidence that nucleic acid duplexes are regular helices rather than asymmetric zippers which does not require accurate knowledge of atomic coordinates. Intuitively, one might expect that molecules with fourfold screw symmetry (like the eightfold helices of *D*-DNA) would crystallise with tetragonal symmetry. They do. Similarly, one is not surprised to find that the 12-fold helices of *A'*-RNA crystallise with rhombohedral symmetry. The crystalline arrangements which would permit 11- or 10-fold helices to exploit the equivalence of many residues and maximise the number of favourable contacts between molecules are less intuitively obvious and might be expected to be rather peculiar. On the other hand, if such peculiar packing arrangements are indeed observed in

polynucleotide crystals, it would be difficult to escape the conclusion that the crystals contained 10- or 11-fold helices. *A*-RNA duplexes which have been described as 11-fold helices by me and my colleagues (*Nature* **211**, 227; 1966) provide a particularly compelling example. *A*-RNA duplexes pack in trigonal lattices containing two sets of close-packed triads. Although the triads are the same size, the contacts within them need not be the same. Indeed, for zipper molecules with no helical symmetry, they could never be the same. For 11-fold helical molecules, the contacts within both triads can be the same provided that the value of a particular packing parameter x is 0.368 or 0.458 (Arnott *et al.* *J. molec. Biol.* **27**, 549; 1967). It is a striking fact that there are two crystal forms of *A*-RNA, one with $x=0.365 \pm 0.005$ and one with $x=0.460 \pm 0.005$. Of course our credulity could be stretched by the argument that helical models should be aban-

doned for *B*-DNA alone among the dozen or so polynucleotide duplexes studied by X-ray diffraction. Fortunately, *B*-DNA crystals exhibit the analogous properties which would be expected of 10-fold helices. The unit cell is rectangular and contains two molecules. If these molecules are 10-fold helices and the number of equivalent contacts is maximised, the ratio of the unit cell sides a and b should be $\tan 2\pi/10$. The remarkable fact is that b/a is $\tan(36.15^\circ \pm 0.25^\circ)$. I find it hard to believe that these crystallographic expectations would be realised so accurately if polynucleotide duplexes in general and *B*-DNA in particular were not close to being perfectly regular helices.

For many years attention was concentrated on the base pairing of DNA. It was right that the backbone should be subjected to similar scrutiny. It is unlikely that any major modification will be needed. $\square$

Improved laser test of the isotropy of space

from Bridget Marx

It might be thought that the most sensitive tests of the special theory of relativity would be those performed on systems travelling close to the speed of light. However, a recent experiment by Brillet and Hall (*Phys. Rev. Lett.* **42**, 549; 1979) which relies on a velocity of only 10^{-4} times that of light has produced one of the most precise tests of the Lorentz transformation, and hence special relativity, yet achieved. The basic ideas of the experiment date from 1887 when Michelson and Morley performed their now classic 'ether drift' measurement. That experiment has been improved, modified and repeated several times in the intervening years with little more than an order of magnitude improvement in sensitivity. The new measurement extends the precision of the previous best null result by a factor of 4,000 in the fractional frequency shift.

The basis of Michelson-Morley type experiments is to look for an anisotropy in the velocity of light travelling in a moving frame of reference. The anisotropy for which Michelson and Morley (*Am. J. Sci.* **34**, 333; 1887) were looking was to be attributed to the effect of the Earth moving through the ether, in which it was supposed that light propagated. They measured the round trip times for light to travel in two per-

pendicular directions by looking at the resultant interference produced between the two arms of an interferometer, and then rotated the whole apparatus. They did not see the expected fringe shift and their resolution placed an upper velocity of 5 km s^{-1} on the Earth's motion through absolute space, in which the ether was thought to be at rest. An improved experiment by Joos in 1930 (*Ann. Phys.* **7**, 385; 1930) reduced the limit to 1.5 km s^{-1} . This was far below the expected value of about 30 km s^{-1} , the Earth's velocity about the Sun.

The null result of the Michelson-Morley experiment is considered very

Fig. 1 Schematic of isotropy-of-space experiment. (From Brillet & Hall *op. cit.*).

Bridget Marx is in the Division of Quantum Metrology, National Physical Laboratory, Teddington.

important to the foundation of Einstein's theory of special relativity. Indeed Robertson (*Rev. Mod. Phys.* **21**, 378; 1949), in an attempt to replace postulate with observation in special relativity, has derived the Lorentz transformation by assuming the existence of a Euclidean rest-frame in which light propagates isotropically and using the idealised results of the experiments of Michelson and Morley, Kennedy and Thorndike (*Phys. Rev.* **42**, 400; 1932) and Ives and Stilwell (*JOSA* **28**, 215; 1938). In Robertson's rest-frame there is a 'metric', with which one can measure space or time intervals, defined as

$$d\sigma^2 = dt^2 - c^{-2}(dx^2 + dy^2 + dz^2)$$

c being the velocity of light in this frame. In an inertial frame moving with velocity v along x the metric is transformed to

$$d\sigma^2 = g_0^2(v)dt^2 - c^{-2}(g_1^2(v)dx^2 + g_2^2(v)(dy^2 + dz^2))$$

If $g_0 = g_1 = g_2 = 1$ then this metric transform is exactly equivalent to the Lorentz transformation. If $g_1(v) = g_2(v)$ then space in the moving frame is isotropic and the Lorentz contraction follows. The three experiments mentioned above measure g_1/g_2 , g_0/g_1 and g_0 respectively. In fact, the fractional frequency shift observed in the Michelson-Morley type experiments determines $1/2((g_2/g_1) - 1)$, which would approximately equal $\frac{1}{2}v^2/c^2$ in the ether theory. The previous best limit to the value $g_2/g_1 - 1$ was that obtained by Jaseja *et al.* (*Phys. Rev.* **A133**, 1221; 1964) and was $\pm 2 \times 10^{-11}$. This was obtained by measuring the beat frequency between two rotating lasers, the cavities of which were perpendicular to each other. Unfortunately, large spurious noise signals limited their sensitivity to only a factor of three better than Joos had obtained.

The new experiment of Brillet and Hall gives a limit on $(g_2/g_1 - 1)$ of $\pm 5 \times 10^{-13}$, which is a significant improvement over the previous results. Their experimental arrangement is shown schematically in Fig. 1. As the length standard they use a single Fabry-Perot etalon, which is mounted on a table rotating in a horizontal plane. Also on the table is a helium-neon laser at around $3.39 \mu\text{m}$ whose output frequency is locked by a servocontrol system to the length of the etalon. Any change in the round trip time of the laser light in the etalon will result in a compensatory frequency shift of the laser, so that the laser wavelength always satisfies a standing-wave condition in the etalon. The etalon is very stable, made of low expansion glass and temperature controlled to within 0.2°C .

Using this kind of servo-system the laser frequency on a non-rotating table is observed to remain constant to within 20 Hz in a 1 s sampling time. The frequency of this cavity-locked laser is compared with that of a stationary helium-neon laser which is locked to an absorption line in methane, and has a similar frequency stability. Isolation of all parts of the system is important, and to this end the methane-stabilised laser is used to lock a third helium-neon laser at an offset of 120 MHz and this is then used to produce a beat frequency with the rotating, cavity-stabilised laser. Faraday isolators prevent feedback from the Fabry-Perot cavity to its laser. The excellent results achieved in this experiment are attributable partly to the attention paid to stability in all parts of the apparatus and partly to the sophisticated signal averaging techniques applied to the beat frequency data. Any spatial anisotropy will manifest itself in a beat frequency change, due to a change in the frequency of the rotating laser, periodic at twice the table rotation frequency. Each reading, which takes approximately half an hour, is the average of many table revolutions and the time dependence of the beat frequency is analysed to select the changes with the right periodicity. The resulting fractional frequency change is of the order of 2×10^{-13} . However, by taking readings at different times of the day and over 100 days this was reduced. A

genuine anisotropy signal will vary in phase according to our velocity direction through space. Spurious signals will remain largely with a fixed phase, and can thus be partly eliminated by looking for a 24-h phase rotation. By also deciding on what is the fixed, isotropic frame with respect to which the Earth is moving, it is possible also to take into account a yearly phase rotation and thus further reduce the spurious background. This averaging is assumed valid as there is no noticeable hour or day dependence of the data. This brings the observed fractional frequency shift down to 10^{-14} for a 24 h average and $1.3 \pm 2.2 \times 10^{-15}$ for the overall average. This result limits $(g_2/g_1 - 1)$, the spatial anisotropy factor in Robertson's derivation, to $3 \pm 5 \times 10^{-15}$. In terms of the ether theory this corresponds to a limiting velocity of about 20 m s^{-1} .

If we assume that the isotropic rest-frame with which we are comparing our moving frame is that in which the cosmic blackbody radiation is isotropic, then the velocity of the Earth is approximately 400 km s^{-1} . Using this velocity the null result of Brillet and Hall, with a resolution (sensitivity divided by predicted ether shift) of about 3×10^{-9} , becomes the most sensitive test of the Lorentz transformation yet performed. If the sensitivity is improved further it might soon be possible to observe the breakdown of this transformation as the anisotropies introduced by general relativistic effects become important.

Eels: new interest in an old problem

from J. D. McCleave and F. R. Harden-Jones

A RECONNAISSANCE expedition to the Sargasso Sea now underway may help to clear up a long-standing mystery. Where are the spawning grounds of the North Atlantic eels?

The American and European eels (*Anguilla rostrata* and *A. anguilla*) of the North Atlantic are very similar in appearance but individuals can be separated by their mean vertebral counts of $107 \text{ s.d.} \pm 1$ and $115 \text{ s.d.} \pm 1$ respectively. The eels are migratory. According to the classical account of their life history they spawn from

January to May in the Sargasso Sea; their pelagic eggs develop into leaf-like larvae—the leptocephali—which drift for $1\frac{1}{2}$ to $2\frac{1}{2}$ years in the ocean currents towards the continental shelves, and here they metamorphose into elvers which swim up the rivers and so into freshwater where as yellow eels they feed and grow. Several years later the adults leave freshwater and run down to the sea. While yellow eels are caught in coastal fisheries it is as silver eels that both species are believed to return to their parent spawning area, to spawn once, and then die.

This account of the life histories of the two eels follows that put forward by the Danish biologist Johannes Schmidt (*Phil. Trans. R. Soc.* **B 211**, 179; 1922). Schmidt based his hypothesis on the size distributions of eel larvae taken in the North Atlantic by Danish research

J. D. McCleave is a Professor of Zoology at the University of Maine, Orono, and F. R. Harden-Jones is a Senior Principal Scientific Officer at the Fisheries Laboratory, Lowestoft and the UK member of the ICES Planning Group for the International Eel Expedition.

vessels and merchant ships. But spawning eels have never been caught in the Sargasso Sea and only four silver eels have been taken off the continental shelf of Europe. No eel eggs have been identified from plankton samples taken in the Sargasso or from any other area. Schmidt used the distribution of the smallest eel larvae taken by research and merchant vessels to define the spawning area for European eels as being bounded by latitudes 20°N and 30°N and longitudes 48°W and 65°W. Although the collection of American eel *leptocephali* was poor, he suggested that this species spawned in a contiguous area somewhat to the southwest.

Schmidt's hypotheses gained general acceptance and his major conclusions were not questioned until 1959 when the English biologist Denys Tucker challenge the "well-publicised saga" (*Nature* **183**, 495; 1959). Tucker offered a "new and drastically different interpretation of the observed phenomena", namely that European eels do not return to the Sargasso spawning ground but perish in continental waters, that European and American eels are not two distinct species, and that eel populations in Europe are maintained by larvae from American eel parentage. This touched off a lively correspondence (*Nature* **183**, 1405; **184**, 1281; 1959; **185**, 589; 1960) with eel workers critical of his new solution. Perhaps Tucker's major contribution was not so much a solution as a reminder that much of Schmidt's story was based on circumstantial evidence. But while most biologists are reluctant to reject the classical account, Tucker's hypothesis has never been disproved, and little weight has been given to Vladikov's point (*J. Fish. Res. Bd Can.* **21**, 1523; 1964) that the presence of American eels in Trinidad and the Guianas in South America is only consistent with a spawning area much farther to the south of that suggested by Schmidt.

There are a number of outstanding questions to answer in the biology of the North Atlantic eels: are there two distinct species; and if there are, where are the spawning areas and when do they spawn; what are the mechanisms for species separation during the period of larval drift; and what are the migration routes and orientation mechanisms of eels in the open sea?

Renewed interest in the life histories of eels developed from the 'Symposium on eel research and management' sponsored by the International Council for the Exploration of the Sea (ICES) and the European Inland Fisheries and Advisory Council (EIFAC) and held at Helsinki in 1976. In part this is attributable to increasing commercial interests and pressure for management. The first sale value of

adults of the two species is about £10 million annually. They are often under-utilised, being processed for pet food in the United States, whereas when smoked they fetch £20 per kg on the Danish retail market and live unpigmented juveniles—'glass' eels—may fetch £500 per kg on the Japanese retail market. Furthermore there is concern for overfishing in some European rivers and the danger is thought to be real in areas where both elvers and adults are exploited. The Helsinki symposium endorsed a recommendation that ICES and EIFAC should organise an International Expedition to the supposed spawning area of the European eel. International support for the venture was enlisted and the Federal Republic of Germany has made the research vessels 'Friedrich Heincke' and 'Anton Dohrn' available for two cruises to the Sargasso Sea early in 1979 under the leadership of F.-W. Tesch of Hamburg. A reconnaissance cruise is now under way.

The possibility of UK support for the Expedition has been discussed by an *ad hoc* group set up by the Royal Society's British National Committee on Oceanic Research and by the Natural Environment Research Council. Although it was agreed that the 'eel problem' raised scientific problems of great interest and merit which deserved further study, it was thought that existing collections of larval material should be properly examined before launching an International Expedition and this view was sustained at a meeting of the ICES Planning Group held in October 1978. Attempts to secure support for an International Expedition have therefore been postponed until the results of the reconnaissance cruises are to hand and the study of existing collections completed.

Progress is being made with the material. All Schmidt's collections from west of 40° longitude, including much unpublished material, are being systematically examined and analysed by Jan Bøetius of Schmidt's old institute, Danmarks Fiskeri-og Havundersøgelser, Copenhagen, in collaboration with E. F. Harding of the Statistical Laboratory, University of Cambridge. Results from the collections of European eel material will be forthcoming but enough is already known to suggest that Schmidt lacked sufficient material to deduce the spawning area for American eels. Examination and analysis of substantial larval collections pertinent to the American eel is to begin soon at the University of Maine in cooperation with other American universities and the National Marine Fisheries Service. At the University of Maine a computer simulation study of larval drift is being developed for the western North Atlantic. The known freshwater distri-

bution of American eels may, in conjunction with these studies, allow a prediction of a likely spawning area for the American eel.

The return of European eels to the Sargasso could be shown directly by their capture at sea and Tesch might succeed in this aim in 1979. Methods other than direct capture are being considered for the future. Large predators may eat eels and their stomach contents could be examined; if the otoliths of adult American and European eels are distinguishable by chemical analysis, scanning electron microscopy or other means, the screening of bottom sediment cores might provide evidence of their distribution; and specific chemicals from mucus or the gonads of mature eels might be detectable in seawater samples, so allowing the presence of adult eels to be deduced without capture.

Nearly 20 years have passed since Tucker suggested that there was but one species of North Atlantic eel. A search has been made for genetically based biochemical differences in haemoglobins, serum proteins, and various enzyme systems. Chromosome number and types have also been examined. But the results of this work have not yet given conclusive evidence for species distinction.

The mechanism for species separation (or the eco-phenotypic separation of Tucker) during larval migration has been assumed to be simply drift from slightly different spawning grounds, differential growth rate and age-at-metamorphosis. That the separation mechanism is imperfect is demonstrated by the arrival, in small numbers, of American elvers in European waters. New collections of larvae to be made along transects into the southwestern North Atlantic during Tesch's 1979 cruises and the examination of existing larval collections and the larval drift simulation study should help to clarify the problem of larval separation.

As no migrating adult eels have been caught off the continental shelves, nothing is known of their migratory routes and nothing is known of their orientation in the sea. Ultrasonic telemetry tracking studies of the movements of migratory eels and displaced non-migratory eels are now being carried out in European continental waters by Tesch and by McCleave. Greer Walker and Arnold (at the Fisheries Laboratory, Lowestoft), and Tesch plans to follow hormonally-treated adult eels in the Sargasso Sea in 1979. But there is undoubtedly a long way to go before the migration of the adult eels can be described in behavioural terms. Nevertheless, the next decade should see a considerable advance in our understanding of the old 'eel problem'. □

SPRING BOOKS

R. A. FISHER was one of the really great scientists of this century, a man of immense ability, with an independent mind of great penetration combined with wide interests and striking erudition. He is, of course, best known for his contributions to statistics and genetics, but he was interested in any variable phenomenon and indeed made a basic statistical contribution to the study of palaeomagnetism, whose implications for the theory of continental drift he both recognised and expounded. All these he combined with a capacity for eccentric behaviour which, though sometimes exasperating or embarrassing to his friends, is now chiefly remembered for its contribution to the seemingly inexhaustible fund of "Fisheriana"—some of it no doubt apochryphal but most of it firmly based on fact. It has indeed been said that in later years, biometrical meetings not uncommonly developed into gatherings engaged in telling endless stories about the master.

I had the privilege (and it *was* a privilege, even if at times a little wearing) of working closely with Fisher, in the Galton Laboratory, for several years in the mid-1930s. They were unforgettable years, and not just because they saw the publication of that great book, *The Design of Experiments* (which Fisher gave as a lecture course while he was writing it), the introduction of such new statistical techniques as discriminant functions, the analysis

of Nabours' data from wild populations of grouse locusts which revealed selective differentials attaining the hitherto unheard of level of 10%, or even the birth of the serological unit which was to unravel the complexities of the *Rh* gene and do so much for the study of human blood groups. They were unforgettable too for the way in which he gave unstintingly of his time in

Life with Fisher

Kenneth Mather

R. A. Fisher: The Life of a Scientist. By J. Fisher Box. Pp.512. (Wiley: New York and Chichester, UK, 1978.) £16.

explaining to a hitherto statistically uneducated young biologist how to approach the analysis of data, including the clarification of the (at any rate, to him) elementary mathematical points at issue, and for his insistence that genetical experiments should be designed with the same care as agronomical experiments, including the calculation of the laboratory resources that would be required. In the case of mouse experiments this was done in terms of mouse-cage-months, and Fisher often based his calculations on optimistic figures for speed and prolificacy of breeding. One soon learned that outright argument about this would serve only to irritate him, but a continuing attitude of concern would lead him to accept a programme more realistic in its expectations, particularly as the numbers of mice failed to mount in the expected way. One learned, also, to look after snails, grouse locusts and dogs as well as mice, and even for one brief period to look after some marsupials which he imported from Australia on the grounds that marsupial genetics had been sadly neglected.

Life with Fisher was indeed a never-ending education. His kindness and patient helpfulness, especially to young people, was something that those of us who benefited from it will never forget. We also saw, however, how coldly and continually hostile he could be to those whom he suspected of being hostile to his views or obstinately misguided in their own. The mid-1930s saw too not only his last polemical

exchange with Karl Pearson but the sad controversy with W. S. Gossett ("Student") with its revelation of a contentiousness so stubborn that it did not even spare an old friend. This contentiousness no doubt sprung from the treatment he had himself received (though not from Gossett) in his earlier struggling years, and it was no doubt also to these early years that we should trace Fisher's deep-seated distrust of accepted authority to whose nature he refers specifically in the introduction to the *Design of Experiments*.

Our personal recollections of this outstanding, and in some ways paradoxical, man can now be filled out and extended by the biography which his daughter, Mrs Joan Fisher Box, has written. It is a lengthy book, but for me at least it made compulsive reading. It supplies us with a full account of his ancestry and early life; and with it we can enter into the life of the Fisher family, its excitements, its happinesses and its sadnesses in a way which is possible only when looking through the eyes of one of the family itself. One can share Mrs Box's nostalgia in looking back at her childhood, as in the brief but touching account of Christmas in the Fisher household, including the story of how on one occasion "the existence of Father Christmas was challenged and one little boy stayed awake and saw for himself the figure who entered and filled the socks; he wore an unfamiliar long gown of

At his desk calculator, Whittinghame Lodge, 1952

scarlet silk, whose pink facings might have revealed to a more sophisticated watcher that Father Christmas was a doctor of science from Cambridge University; a mask with curling silver beard hid his features". This is true Fisher and a worthy addition to our store of Fisheriana. Nor does Mrs Box burke the sad story of the break-up of Fisher's marriage. She paints her father's picture in a way that would have met with Cromwell's approval—"warts and all": blemishes as well as greatness.

It would, however, be wrong to leave any impression that the book is wholly, or even mainly, devoted to Fisher's family life and personal matters. On the contrary Mrs Box presents a full account of his scientific life, his scientific interests and scientific achievements, with which the more personal things are interwoven, as indeed must have been virtually inevitable in writing about Fisher. The early years,

before 1919, not only bring in reference to the paper he gave while still an undergraduate in 1911, in which his interests in biometry and genetics are foreshadowed, but also cover his two early major works on the exact distribution of the correlation coefficient and the correlations between relatives on the supposition of Mendelian inheritance—the latter now a genetical classic.

He went to Rothamsted in 1919, initially for such time as a grant of £200 would cover, but stayed until 1933. During these fourteen years he recast the whole theoretical basis of statistics and developed the modern methods of designing and analysing experiments, while at the same time he was generating his theory of the evolution of dominance and writing his seminal book *The Genetical Theory of Natural Selection*—and this genetical work was all carried out in his spare time.

When he succeeded Karl Pearson at

the Galton Laboratory in 1933, he was able further to develop his genetical interests by undertaking genetical experiments on a sizeable scale and by founding the serological unit. But a wealth of statistical work continued, including the sharp defence of his basic approach against those who chose to criticise it. Much the same balance of interests continued in Cambridge where he succeeded R. C. Punnett as Professor of Genetics in 1943. The Cambridge days saw the publication of the *Theory of Inbreeding*, arising from some of his mouse experiments, and also *Statistical Methods and Scientific Inference* in which he discusses at length the problems and logic of inductive inference. They also saw the flowering of the serological unit and the recognition by many honours from universities and academical bodies in a number of countries, as well as by the knighthood conferred on him in 1952. He travelled widely, especially in the USA and India where his ideas had a great influence, and after retirement in 1958 his Australian friends persuaded him to make his base in Adelaide where he died in 1962.

Each period of his life can be seen as marked by its distinctive scientific achievement, springing from the problems which his various appointments posed and the opportunities which they offered. It is a fascinating story which Mrs Box has to tell, and she tells it well. Her presentation and assessment of his work is comprehensive, balanced and informative, and she points to limitations where she sees them, as for example in Fisher's much smaller interest in the direct study of the hereditary materials than in the numerical relations to be found in breeding experiments.

This is indeed a fascinating book. To those who knew and worked with him it will bring the special pleasure of recalling a past association that was both memorable and eventful. To a wider audience it offers an account, at once informative and human, of a great scientist who gave us statistics as we now know it, while at the same time establishing himself among the great leaders of genetics especially in the study of natural selection and its impact on populations and their properties. □

Kenneth Mather is Honorary Professor of Genetics at the University of Birmingham, UK.

Morgan's crisis

C. D. Darlington

Thomas Hunt Morgan: The Man and His Science. By G. E. Allen. Pp. 447. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1979.) \$31.50; £15.80.

DURING his life the work of Thomas Hunt Morgan was the centre of many disputes. The chief of these concerned the validity of his famous discovery: Were the chromosomes the physical basis of heredity? Others concerned secondary questions: What did the discovery mean? How was it made? And who made it? The first question for long divided the scientific world into battling parties. The others divided only the new believers who in the course of 50 years have taken possession of the battlefield. For them the secondary questions have grown in importance. And for their solution the life of this enigmatic man has become of absorbing interest.

We now have two books on Morgan from outside his scientific circle which help us to answer these questions. One is a concise but accurate and convincing account by Shine and Wrobel (Kentucky University Press, 1976). The other is this larger treatise by Allen. Neither comes to grips with the crucial issues, perhaps because no one can who was not himself in the fray. Before it is too late, therefore, we should recall how those issues came to a crisis as they did for Morgan in the spring of 1910.

It was the meeting of two apparently conflicting ideas which created this crisis. Both had come from Europe to the United States in the course of Morgan's teaching life. They had been brought by two unconnected missionaries. One of these was E. B. Wilson who had become the head of Morgan's department at Columbia University. The results of his visits to Europe in 1883 and 1892 were concentrated by Wilson into the three editions of his great book, *The Cell*; a book which cost him the labour, not of one decade (as Dr Allen supposes), but of a lifetime. It was a book which argued the central position of the chromosomes in heredity and development.

The other missionary was Bateson, whose journey from England was different in period, scope and direction. His Silliman lectures in 1907 had argued the central position of Mendelism in the study of heredity. And they had converted to his view several shrewd critics at Yale and at Harvard, notably East on the plant side and Castle on the animal side.

So two schools, sharply divided, came into being in the United States. Neither seriously converted the other. And neither in the least converted Morgan. Indeed it seemed that 20 years of embryological experiment had left Morgan without any theory of his own and ostentatiously sceptical of everybody else's. He doubted Wilson's chromosomes. He ridiculed Bateson's factors. He confused Darwin's origin of species with his natural selection, which he even condemned as teleological. And (to use Allen's word) he "chastised" Weismann for his errors. He paid some respect to the mutation theory of de Vries. But when in 1907 Fernandus Payne, his pupil jointly with

Wilson, asked him for a problem he gave him the Lamarckian task of breeding Castle's *Drosophila* in the dark for 60 generations.

Payne, as he recalled 67 years later, failed to diminish the fly's eyes by two years' life in the dark. But Morgan himself, in the third year, with a hand lens, was able to find something in the light, a mutation, a single male fly with white eyes. The factor responsible proved to be, as it was likely to be, in the unpaired sex chromosome. From this one fly Morgan could therefore with little trouble demonstrate Mendelian segregation, sex-determination by chromosomes, and sex-linkage. Even, if he had thought of it, he could have seen a ratio distorted by natural selection. The progeny of this one fly corrected unmistakably all Morgan's recent mistakes.

In this embarrassing position Morgan quickly wrote a letter to *Science*. Then on 7 July, 1910, writing from Wood's Hole (although Dr Allen does not seem to know) he sent the much corrected typescript to Bateson at Cambridge, offering to share with him his stocks and the theory they might carry with them. Bateson, however, had come to distrust Morgan's judgement and he evidently declined the stocks; he also certainly rejected the theory.

Having failed to enlist Mendelian support, Morgan, back in New York, turned to the chromosome side, to Wilson in the next room to his own. Wilson was able to tell Morgan about the Belgian cytologist, Janssens, who from seeing chiasmata between chromosomes at meiosis recalled, as German cytologists had done earlier, Weismann's theory of meiosis. This theory demanded recombination which would arise by "crossing over" and would explain linkage. Wilson was also able to recommend to Morgan three pupils who had learnt about the chromosome theory from him, and about Mendelism from the books of Bateson's disciples, Punnett and Lock. They would breed his flies.

The results in the fly-room were dramatic. But what exactly happened? The answer I partly discovered for myself when twenty years later I questioned the two leading figures in the drama. Who did it, I asked Wilson; and his reply was quite firm. Morgan's three greatest discoveries, he said, were those three men, Bridges, Sturtevant and Muller. Then I asked Morgan what Janssens' idea had meant for him. Janssens, Morgan replied, being a Jesuit, had seen his problem not scientifically but teleologically. His idea of crossing over must have come from the belief that there could not always be four products of meiosis in all sexual reproduction unless all four were different. Morgan clearly had not read

Nobel Prize was announced, 1935

Courtesy Dr Tove Mohr

Janssens' article. He did not know that in his first sentence Janssens deduced his argument from Weismann, that is, from the belief that only with recombination could natural selection be made to work. I sadly concluded that Morgan had never understood, and perhaps had long made up his mind not to understand, the chromosome side of the chromosome theory.

The gaps in understanding between Wilson, Morgan and Bateson were profound. How profound is shown by their continuance today, and by the failure of Morgan's biographer to notice them. For this reason he does not realise that the process of crossing-over between chromosomes has never been seen in female *Drosophila*. He does not realise that it remains, as Morgan would have said before he inferred it, a pure speculation. Nor does Allen realise the fear Morgan had of discussing the other side of the story, the absence of crossing over in the male *Drosophila*. Was its purpose perhaps to make his experiments possible? We shall never know.

For over 20 years Morgan had demanded facts and denounced speculation. But now, swept forward by the success of his clever young men, he found himself inscribing his name as the head of a grand speculative movement. Dr Allen devotes proper attention to those three young men: Bridges, the quiet easy-going countryman from the north, whose keen eyes discovered hundreds of mutations;

Sturtevant, the observant horse-breeder from the south whose ingenious experiments and interpretations carried him beyond heredity into development; Muller, the intense excitable New York Jew whose imagination went too fast and too far for Morgan's understanding or forbearance.

These men did not create a unified genetic theory. That was too much to expect. But they put together the assembly line of a great *Drosophila* industry. Surely no city but New York at that time could have brought together such a combination of talent. And if Morgan had a "creative genius" as Dr Allen calls it, it was that, when he saw what they could do, he let them do it.

The defect of this *Drosophila* industry lay in the limitations of the fly. It failed to reveal the chromosome processes underlying its heredity and indeed heredity in general. The diosophilists had to avoid meiosis. Making a virtue of necessity, Muller therefore quickly went beyond the chromosome to the gene. There the reluctant Morgan followed him to adopt the gene as his own. The chromosomes could then be taken for granted. Reversing the order of Nature the chromosomes did what the fly required. This was Morgan's "Theory of the Gene".

After the lapse of years Morgan, having lost interest in the experiments of genetics, and never having sustained an interest in its ideas, was awarded a Nobel Prize. Dr Allen's account allows us a glimpse of the embarrassment that once again overtook him. Having delayed his journey to Stockholm, on his way he arrived in Edinburgh still uncertain what, and whom, and how much, he should acknowledge. Such a failure to sort out his intellectual antecedents might be thought to be a merely personal problem and one not uncommon in science. But in this case, its effects have survived far beyond any personal interests. The hiatus in the relations of Morgan, with Bateson on the one hand, and with Weismann, Boveri, Janssens and Wilson on the other, has left its traces in the dichotomy of genetics as it is taught today, a defect liberally illustrated in the present biography.

The Nobel Prize had been heralded by a last general discourse, a book of lectures unhappily entitled *The Scientific Basis of Evolution*. In the one original chapter in this work Morgan finds himself trapped with the too obvious notion that the evolution of man introduces a new biological principle. In his view there are now "two processes in inheritance" in man. The inheritance of culture, he explains, is now independent of the old limitations of genetic inheritance as under-

In the Fly Room at Columbia. "Who combed my hair?" Morgan asked when he saw this snapshot

stood, for example, in the fly.

It is surprising that Julian Huxley in a book on evolution which he dedicated to Morgan should have adopted this fallacy of Morgan's 30 years later as his own. Without apparently knowing its source he described it as "psychosocial inheritance". But it is even more surprising that Morgan's biographer, claiming to be a Marxist (who should always know what he is going to discover), has now failed to notice this gem of Marxist dialectic: for here is an idea which opens the way so agreeably to Lamarckism and Lysenkoism. From it the whole froth of our social sciences today, with their specious arguments and calamitous consequences, easily flows and overflows.

Dr Allen must have occupied many years in preparing this work, as his method of assembling it is a recipe for chaos, chaos in writing and chaos in reading. His accommodation of Bateson (and the present reviewer) at the John Innes Horticultural "School" which he places in Merton College, Cambridge, is an extreme example. But what can be expected of a writer who buries his references irrecoverably in 743 footnotes dispersed throughout the text? Clearly his book may help later enquirers into the history of genetics. But not unless they are willing to start at the beginning again, however distressing the results of their enquiries may be. □

Master of biological research

M. R. Pollock

Selected Papers in Molecular Biology. By Jacques Monod. Edited by A. Lwoff and A. Ullmann. Pp. 753. (Academic: New York, San Francisco and London, 1978.) \$29.50; £19.15.

No doubt there will always be some scientists, overburdened by the appalling mass of literature that has to be sifted through these days, to protest against the publication of reports that have already appeared in print and are generally available in libraries. But there must be many more who will warmly welcome this collection of papers by Jacques Monod, who was unquestionably one of the greatest of the architects and exponents of the new biology. It is, in fact, a selection of less than half his total output of 131 scientific papers and, rather unfortunately, does not include any of his forewords, essays, reviews or recorded interviews on broader themes, which are less easy to get hold of than the others. Indeed, there must be many who would have liked an unexpurgated collection of *The Complete Works*. He was a master of beautiful and clear writing, both in French and English, and his views on almost everything are worth reading.

Presumably the basis of the editors' selection was to avoid redundancy of material and the extravagance of two volumes. The 62 papers reprinted make a fair-sized book which, priced at over £19, seems expensive enough for something in principle already available, but still less than half what would have to be paid for loose xerox copies. The volume is generally well produced and only relatively few articles have had to be reduced to an extent where the size of print is borderline for easy reading. A fair proportion of the papers excluded are abbreviated preliminary reports appearing in *Comptes rendus* . . . , completed versions of which are published elsewhere; but there are some apparent inconsistencies. An introductory explanation of the selection principles used would in any case have been interesting and reassuring.

The book in itself is a great tribute to the work and genius of Jacques Monod. "Occasionally the career of a scientist", write the editors in their preface, "is marked by an important discovery. It is most unusual that it be

illuminated by an uninterrupted series of great discoveries and still more unusual when each discovery gives rise to new concepts and opens new vistas". But it is much more than just a tribute. It is a story, told in the dry, restricted language which research workers are expected to use for recording what they have done and how they think, of one man's contribution to scientific knowledge. And, apart from a very few pieces of work mostly at the beginning of his career, it is the story about a single problem: the specific control of enzyme production in living organisms. This problem originally presented itself, apparently rather narrowly, as the phenomenon of 'enzyme adaptation' in microorganisms and it was tackled by Monod mainly through the

Jacques Monod

Camera Press

study of a single system: the famous β -galactosidase of *E. coli*; but it carried with it tremendous implications for a better understanding of the wider problem of the phenotypic expression of genetic potentiality in general.

But heaven forbid that anyone should read the book like a story from beginning to end! It is, rather, a book of reference and inspiration, to be consulted by research students in order to learn something about how a master of biological research thought and worked, and for historians to understand better thereby the evolution of ideas in one area of biology covering less than 30 years: a period, however, that comprised the profound revolution in our thinking in genetics, biochemistry and ultrastructure which we now call molecular biology.

This period in Monod's work

stretched over only 20 years: from the late 1940s, during which he wrote his first long classic review on 'enzymatic adaptation', published in *Growth*, to his Nobel prize article of 1966. To get a proper perspective, it is illuminating to read these two articles directly in sequence. In the first, the problem was defined, the essential questions posed and some tentative, plausible mechanisms (often incorrect, but that is not the point) suggested. In the last, most, if not all, the questions had been answered.

In between, Monod had master-minded developments crucial to providing the answers. These include (amongst others) the discovery that specific inducers of enzyme formation are not necessarily even ligands of the enzyme, let alone substrates (1950); the illuminating application of the 'allometric plot' to the study of the kinetics of enzyme induction (1952); the demonstration (1954) that enzyme induction involved *de novo* biosynthesis of the specific enzyme protein from amino-acids; specific 'permeases' (1955); and the discovery (1958) that the inducer operated by antagonism of a specific gene-determined repressor. Thereafter followed the 'presentation' of a veritable avalanche of new concepts: 'structural' and 'regulatory' genes, the 'operator', the 'operon', the 'promoter', and finally (1962) the property of allostery which is of fundamental importance to the understanding of the control of enzyme function and enzyme synthesis.

In nearly all these developments Monod played a vital—usually a completely dominant—role, although it is important to realise that outstanding colleagues such as Mel Cohn and François Jacob (and indeed several others whom he guided and stimulated in his inimitable fashion) often also played an important—and sometimes essential—part; not forgetting André Lwoff himself who provided, right from the beginning, the emotional, intellectual and material background support without which almost everything would have been five times more difficult.

Monod's essential talent lay in his ability to combine a precise, logical formulation of a problem (that is, in terms that could be tackled experimentally and had meaning within the current 'paradigm') with an imaginative grasp of its implications in biology as a whole, and the power to initiate plausible interpretations yet move on from a concept, however attractive, once it was beginning to obstruct, rather than promote, the development of a subject. The difficulty, of course, is to recognise the obstruction. It is failure to do this that so often prevents research workers from making original discoveries. And nowhere is this better illustrated than in Monod's final rejection

Royal Society of Medicine International Congress and Symposium series No. 7

New Advances in the Treatment of Candidal Vaginitis

edited by D. Gough

May/June 1979, approx. 55pp., £4.50/\$9.25 (Paper 0.12.791706.3 (Academic Press))

Contents include

S. R. Mayhew and W. E. Suffield: A study of the efficacy of seven-day administration of miconazole in candidal vaginitis. D. Gough: The influence of dosage and duration of administration of miconazole on the cure and relapse of candidal vaginitis. M. Borgers and M. De Brabander: Differential effects of imidazole anti-fungal drugs on the yeast and mycelial phases of *Candida albicans* in vitro. A. Reyntjens: New gynaecological formulations of miconazole. W. Denald: A study on the cure and relapse of candidal vaginitis with a novel formulation of miconazole.

Published jointly by the Royal Society of Medicine, Academic Press and Grune & Stratton

Information Transmission in the Nervous System

M. Uttley

May/June 1979, xiv + 102 pp., £7.50/\$15.50 0.12.709750.3

In this monograph the author puts forward a hypothesis about synaptic variability which offers an explanation of psychological findings in terms of neurophysiological facts, and which is applicable to phenomena at all levels in the nervous system, from single neurones to the whole animal. The hypothesis is described by a single equation from which numerical predictions can be made, and in the first four chapters it is fully discussed together with its consequences in simple situations and its computer simulation in complex situations. The book will undoubtedly be read with great interest by a wide variety of students and researchers in psychology and neurophysiology.

ASA Monographs

18. Social and Ecological Systems

edited by Philip Burnham and Roy Ellen

May/June 1979, approx. 330pp., £8.80/\$18.25 0.12.146050.9

Contents include

James J. Fox: A tale of two states: ecology and the political economy of inequality on the island of Roti. David R. Harris: Foragers and farmers in the Western Torres Strait Islands: an historical analysis of economic, demographic and spatial differentiation. Pierre van Leynseele: Ecological stability and intensive fish production: the case of the Libinza people of the Middle Ngiri (Zaire). Paula Brown: Change and the boundaries of systems in highland New Guinea: the Chimbu. Jonathan Friedman: Hegelian ecology: between Rousseau and the world spirit. Tim Ingold: The social and ecological relations of culture bearing organisms: an essay in evolutionary dynamics.

Society for Applied Bacteriology Technical Series No. 12

Plant Pathogens

edited by D. W. Lovelock

May/June 1979, xii + 122pp., £9.60/\$19.75 0.12.457050.X

Plant pathology is an area in which significant advances are continually being made. This reflects the perennial interest of agricultural and horticultural microbiologists in plant diseases and in the relationship between the causative organisms and the environment. This book records the proceedings of a Demonstration Meeting of The Society for Applied Bacteriology, at which the participants exhibited techniques that they had developed and found useful in the study of plant pathogens. They discussed techniques for use in field study and others that are more suited to the research laboratory. Some of these methods are completely new and can be used in different circumstances and in the study of other species.

Origin, Prevention and Treatment of Affective Disorders

edited by Mogens Schou and Erik Strömgren

April/May 1979, xiv + 308pp., £9.80/\$20.25 0.12.628950.6

In 1978, the University of Aarhus, Denmark, arranged a series of international scientific symposia to celebrate its 50th anniversary. The university wanted to emphasize the internationality of research and to provide opportunities for discussion of the results of past work and the plans for future work. The topics of the symposia were therefore related to the dominant fields of research of the institutes which organized the symposia. The Institute of Psychiatry held a 3-day symposium with Danish and international speakers on the topic of affective disorders, with the emphasis on origin, prevention and treatment, which is the subject of this book. The presentations dealt with lithium therapy and research, rapidity, tryptophan, brain amines, blood and tissue antigens, cerebral localization of memory and depression, neuroendocrinology, genetics, epidemiology and suicide.

Methods in Microbiology Volume 12

edited by T. Bergan and J. R. Norris

April/May 1979, xvi + 268pp., £12.00/\$24.75 0.12.521512.6

Contents of Volume 12

S. D. Henriksen: Serotyping of bacteria. E. Thal: The identification of *Yersinia pseudotuberculosis*. T. Bergan: Bacteriophage typing of *Yersinia enterocolitica*. S. Winblad: *Yersinia enterocolitica* for serotype 0-8. S. Muckerjee: Principles and practice of typing *Vibrio cholerae*. H. Brandis: Vibriocin typing. P. Oeding: Genus *Staphylococcus*. J. Rotta: Group and type (groups A and B) identification of haemolytic streptococci. J. Jelinkova and J. Rotta: Identification and typing of enterococci. H. Brandis: Bacteriocins of streptococci and bacteriocin typing. E. Lund and J. Henriksen: Laboratory diagnosis, serology and epidemiology of *Streptococcus pneumoniae*. Subject index.

Pulmonates Volume 2B: Economic Malacology

with particular reference to *Achatina fulica*

A. R. Mead

April/May 1979, x + 150pp., £12.00/\$25.20 0.12.267541.X

From a Review of Volume 1

'... a stimulant to further research. As a record of what has been achieved in many areas and a pointer to what can be done, this book should take its place on the shelves of research departments.' Joyce E. Rigby in *Nature*.

Contents

Introduction. Dispersal to new areas. Evaluation of dispersal. Economics. Bionomics in control. Biological control. Other methods of control. Disease and decline. Evaluation of control. Future prospects.

Transactions of the Zoological Society of London

Editor: H. Gwynne Vevers

Publication: Volume 35, No. 1

April 1979, approx. 90pp., £12.50/\$26.25

Contents of Volume 35, No. 1 by M. N. Bruton

The breeding biology and early development of *Clarias gariepinus* (Pisces: Clariidae) in Lake Sibaya, South Africa, with a review of breeding in species of the subgenus *Clarias* (Clarias). The food and feeding behaviour of *Clarias gariepinus* (Pisces: Clariidae) in Lake Sibaya, South Africa, with emphasis on its role as a predator of cinchids. The role of diel inshore movements by *Clarias gariepinus* (Pisces: Clariidae) for the capture of fish prey.

Research on Steroids Volume VIII

Proceedings of the Eighth Meeting of the International Study Group for Steroid Hormones

edited by A. Klopffer, L. Lerner, H. J. van der Molen, and F. Sciarra

April/May 1979, xii + 384pp., £15.60/\$32.25 0.12.416050.6

This volume contains the proceedings of the VIII Meeting of the International Study Group for Steroid Hormones, held at the Consiglio Nazionale delle Ricerche, Rome, from 5–7 December 1977. The topics under discussion were 'Control Mechanisms of Reproductive Function' and 'Recent Methods in Steroid Assay'. The reports of recent research covered subjects ranging from blastocyst steroids to mechanisms of action of progesterone on oocytes, hormonal regulation of sertoli cell function and steroid receptors in the testis. The sections on new techniques included details of enzyme immunoassay and affinity chromatography for steroids.

Nonsense Mutations and tRNA Suppressors

edited by J. E. Cells and J. D. Smith

May/June 1979, approx. pp., £16.00/\$33.25 0.12.164550.9

From the preface:

'This book is a record of the proceedings of the EMBO Laboratory Course and Aarhus University 50 Years Anniversary Symposium on "Nonsense mutations and tRNA suppressors" held in Aarhus in July 1978. ... The main aim of the book is to introduce the reader to the field of translational suppression, specifically to nonsense mutations and tRNA suppressors. The book covers classic work on nonsense suppressors in prokaryotes and yeast as well as the latest developments in the search for nonsense mutations and tRNA suppressors in higher eukaryotes. To help the reader the book contains a few general chapters dedicated to tRNA and its role in protein synthesis as well as a compilation of wild type and mutant tRNA sequences.'

Applied Biology Volume 4

edited by T. H. Coaker

May/June 1979, xii + 286pp., £16.40/\$34.44 0.12.040904.6

From a Review of a Previous Volume

'... fills a valuable niche and the high standard of production gives it an assured place on the library shelf.' B. N. K. Davis in *Biological Conservation*.

Contents

N. W. Pirie: Leaf protein as a source of food. C. R. Field: Game ranching in Africa. John H. Steele: Some problems in the management of marine resources. M. S. Johnson and A. D. Bradshaw: Ecological principles for the restoration of disturbed and degraded land. W. Clive James and P. S. Teng: The quantification of production constraints associated with plant diseases. Subject index.

Kidney Transplantation

Principles and Practice

edited by P. J. Morris

May/June 1979, xviii + 310pp., £17.50/\$36.25 0.12.507450.6 (Academic Press) 0.8089.1142.2 (Grune & Stratton)

This book presents the current position of renal transplantation from the point of view of the practising physician, transplant surgeon, nephrologist, tissue typer, virologist or bacteriologist. The book is comprehensive in the sense that a person entering a transplant unit for the first time could get an overall grasp of kidney transplantation, ranging from the surgical techniques to the diagnosis and pathology of rejection. Thus the book should be of value to all who are involved in the various aspects of kidney transplant programmes, be they doctors, scientists or nurses.

Advances in Microbial Physiology Volume 18

edited by A. H. Rose and J. Gareth Morris

April/May 1979, X + 300pp., £18.60/\$38.50 0.12.027718.2

This series presents critical review articles on all aspects of the physiological and biochemical activities of micro-organisms. *Advances in Microbial Physiology*, spanning the area between microbiology and biochemistry, is able to deal with subjects of interest in both fields which previously have received little attention from reviewers.

Contents of Volume 18

R. H. Garrett and Nancy Klein Amy: Nitrate assimilation in fungi. Paul S. Sypherd, Peter R. Borgia and John L. Paznokas: Biochemistry of dimorphism in the fungus *Mucor*. Michael G. Sargent: Surface extension and the cell cycle in prokaryotes. W. R. Finnetry: Physiology and biochemistry of bacterial phospholipid metabolism. Author index. Subject index.

Food Texture and Rheology

edited by P. Sherman

June/July 1979, approx. ??? pp., £20.00/\$41.50 0.12.639960.3

This book provides an up-to-date appraisal of current thought, developments and practice in the study of food texture. It contains papers which were presented at a recent symposium held in London and organised on behalf of the International Union of Food Science and Technology. The papers offer critical reviews of the present state of knowledge as well as reports on recent original research on food texture. Subjects treated range through the sensory evaluation of textural properties; instrumental test methodology for textural properties and problems encountered in instrumental testing; and the rheology of vegetable proteins, of dough and baked produces and of miscellaneous food products.

Recent Advances in the Biochemistry of Cereals

edited by D. L. Laidman and R. G. Wyn Jones

June/July 1979, approx., 400pp., £21.00/\$43.50 0.12.433950.6

This volume contains the published proceedings of the 16th annual conference of the phytochemical society of Europe. Contributions are mainly concerned with factors regulating processes at a cellular level. They include the biochemistry of mineral ion uptake, grain germination encompassing dormancy and vigour phenomena, and the development of the seed particularly in terms of its carbohydrate, protein and lipid content, and the significance of grain composition in nutrition and food technology. Plant biochemists, plant physiologists, agriculturalists and food scientists should find much to interest them in this book.

Medical Physics series

Non-Invasive Physiological Measurements Volume 1

edited by Peter Rolfe

May/June 1979, xiv + 350pp., £21.00/\$43.50 0.12.693401.7

The aims of this book are to provide a comprehensive description of the techniques for physiological measurement which are presently available, to assess the clinical and research value of each, and to indicate where further developments are needed and likely to occur.

Contents include

An introduction to non-invasive cardiodiagnostic techniques. Quantifying skin disease and *in vivo* using electrical impedance measurements. Electrical impedance pneumography. Ultrasonic Doppler velocimetry. Cerebral blood flow measurement using venous occlusion plethysmography in the newborn human infant.

Analytical Methods for Glycerol

M. R. F. Ashworth

May/June 1979, xii + 220pp., £21.00/\$43.50 0.12.065050.9

As regards its completeness, this book has no rival in its field. It includes sections on oxidation methods, esterification methods, ether formation, dehydration, reactions, physical and non-chromatographic separation methods and chromatographic methods. There are chapters for methods with glycerol compounds and for the enzymic determination of glycerol, each chapter separated into sections, each section comprehensive. Thesis workers in the field of organic chemistry, laboratory staff engaged in organic and biochemical work, and users of university chemical libraries all over the world will know the author as a distinguished specialist in the field of organic analysis.

Electron Spectroscopy

Theory, Techniques and Applications Volume 3

edited by C. R. Bundle and A. D. Baker

April/May 1979, x + 362pp., £21.50/\$45.15 0.12.137803.9

From a review of Volume 1

"A book to be wholeheartedly recommended not only to photoelectron spectroscopists, for whom it will become a standard reference, but to that much wider audience of chemists and physicists who are interested in, or need to know about, the electronic structure of the chemical bond."

D. S. Urch in *Chemistry in Britain*

Volume 3 largely moves away from the theme of the first two volumes, which discussed photoelectron spectroscopy exclusively, by including discussions on X-ray emission spectroscopy, electron impact spectroscopy, and ion fragmentation mechanisms.

Air Pollution Chemistry

John D. Butler

April/May 1979, x + 408pp., £25.00/\$52.50 0.12.147950.1

The presence of chemicals in the air poses questions about their concentration, toxicity, distribution, stability and influence on climate. The aim of this book is to introduce the methods used to answer these questions and assess the current knowledge and ideas about air pollution. Although written from the viewpoint of a physical chemist and dealing with the applications of chemistry to air pollution, little chemical knowledge has been assumed. Wherever possible concepts have been explained and defined before their application, thus making the text readily comprehensible to specialists in other disciplines.

The Electrochemistry of Lead

edited by A. T. Kuhn

May/June, xviii + 468pp., £28.00/\$59.00 0.12.428350.0

The studies in this book, now revised and expanded from their original form, are derived from a Symposium at the University of Salford on the same subject. Subjects covered include the electrodeposition of lead and its alloys; the electrochemistry of lead in molten salts; the use of lead-dissolving electrolytes whether in refining of the metal, in reclamation of scrap lead, or as the basis of a new battery; hydrogen evolution on lead; and lead dioxide anodes. Although not intended to be a book primarily about the lead-acid battery, the work considers in detail the electro-chemistry of the lead-water-sulphuric acid system, much of it 'battery-orientated'.

Food Science and Technology: A series of Monographs

Food Microscopy

edited by J. G. Vaughan

April/May 1979, xvi + 652pp., £29.60/\$61.25 0.12.715350.0

Modifications to the light microscope and the development of the electron microscope have greatly increased the importance of microscopy in the practice of food science. However, no comprehensive account of these advances has yet appeared. This book breaks new ground in showing how light and electron microscopy can be used to investigate problems of food processing, acceptability and deterioration. It also covers the problem of the identification of food constituents, which has been intensified by recent legislation, particularly with regard to animal feeds. The book will be of interest and forensic scientists, biologists and microscopists, and for undergraduates in departments of Food Science, Biology and Nutrition at universities.

Proceedings of the 11th International Power Sources Symposium Power Sources 7

Research and Development in Non-mechanical Electrical Power Sources

edited by J. Thompson

May/June 1979, xii + 774pp., £65.00/\$134.50 0.12.689150.8

The importance of the biennial International Power Sources Symposia, and the series of books that records their proceedings, continues to increase. This volume contains the 49 papers presented at the 11th Symposium, held in September 1978 and attended by some 450 delegates from 30 countries. The contributors are drawn, principally, from Government research establishments, industry and universities, and the Symposium provided them with a forum within which they were able to present and discuss their own progress in the study, development and use of electrical power sources. Their major concern was with the many types of primary, secondary, high-temperature and reserve batteries, fuel cells and other types of non-mechanical power sources.

tion of the cloying, but once attractive, hypothesis that the close similarity between the specificities of enzyme induction and enzyme function must mean that the mechanism of induction involves combination between the inducer and a receptor molecule consisting at least of a modified version of the enzyme, if not the enzyme itself. But the essential point to be grasped was that the relationship is functional, not chemical. Once Monod had discarded the false implications of the specificity similarities, he was free to

postulate the true nature of the receptor, characterise and define the *lac* repressor and discover the phenomenon of allostery.

Thus, almost more than from the actual discoveries themselves, we can benefit from studying the way he used his mind. And that is one of the chief reasons why this collection of masterpieces is so valuable. □

M. R. Pollock is Emeritus Professor of Biology at the University of Edinburgh, UK.

Strategies of dissent

Vera Rich

To Build a Castle: My Life as a Dissenter. By Vladimir Bukovsky. Pp.352. (André Deutsch: London, 1978.) £7.50.

IN 1961, Vladimir Bukovsky was a biology student in Moscow. Today he is a biology student in Cambridge. *To Build a Castle* relates the history of the intervening years, which, with a few brief intervals of relative freedom, were spent in the prisons and psychiatric hospitals of the USSR.

This period spans the rise of dissent and opposition in the USSR. One curious feature of the dissent movement is that, at least in Russia proper, scientists played a major role, and at the beginning, the leading role. (In the non-Russian republics, such as Lithuania and Ukraine, other factors such as national aspirations make the picture more complex.) At one end of the dissent spectrum, leading scientists could defy the régime from a position of strength, knowing that the state needed their expertise; at the other, it was among the students of the natural sciences that latent doubts began to take a more concrete form—total ideological conformity and commitment being ensured in the humanities and social sciences by the preliminary screening of University entrants.

Bukovsky's book outlines how such doubts could grow and crystallise in a student living in the immediate post-Stalin era. After his expulsion from the University in 1961, we follow him through the long routine of arrests and incarcerations. This book is not, however, just another set of labour-camp memoirs. The *Castle* of the title is an imaginary one, which Bukovsky patiently constructed in his mind through long years in prison and psychiatric ward, as a means of

therapy and self-protection against the grim reality which surrounded him.

Accordingly, the main interest in the book is to be found in what may be called the strategies of dissent. Nowadays, it is taken for granted that any civil rights protest is essentially a demand that what is guaranteed by the constitution should be implemented in fact. Zhores Medvedev, the geneticist, for example, waged a major campaign against Soviet censorship on the grounds that "Secrecy of correspondence is guaranteed by law". Bukovsky relates how this procedure was first developed in the late 1960s and how, when Alexander Yesenin-Volpin, the mathematician, first urged it, many budding dissidents were sceptical of its potential value—a scepticism which, as Bukovsky describes, has been refuted over and over again in the past decade.

Most fascinating, however, are the chapters dealing with Bukovsky's experiences of mental hospitals, for here we have the first-hand background to the reports which Bukovsky, in a brief spell of freedom, managed to transmit to the West. These reports for the first time drew attention to the new Soviet theory that political discontent equals mental disorder. Here too is the practical experience of psychiatric examinations and medical "commitments", which led Bukovsky, in collaboration with psychiatrist Semeon Gluzman, who is still serving a seven-year sentence in a labour camp, to write their famous *samizdat*, *Manual of Psychiatry for Dissidents*. This is a slim but detailed handbook of how to behave under interrogation, with some pungent analyses of the main psychological types of interrogator likely to be encountered, and the best strategies for circumventing and frustrating them. In a book of the stature of *To Build a Castle*, it is regrettable that space could not have been found to include the 'Manual of Psychiatry' as an appendix—this is, however, one of the few faults one can find with an otherwise excellent work. □

Vera Rich is Nature's regular correspondent on Soviet and East European affairs.

FROM CHURCHILL LIVINGSTONE

A major new textbook

FUNCTIONAL HISTOLOGY A TEXT AND COLOUR ATLAS

Paul Wheater, George Burkitt, Victor Daniels and Philip Deakin

1979 288 pages 387 colour, 83 black and white and 69 line illustrations
paperback £12.00 / hardback £20.00

A unique and wholly intelligible picture of human/mammalian tissues.
To be published June, 1979

Eye-opener on life

A. J. Cain

Life on Earth. By D. Attenborough. Pp. 319. (BBC/Collins: London, 1979.) £7.95.

THIS pleasant book is not, and was not intended to be, anything like a scientific text. Although based on the highly successful television series, it is also far from a mere coffee-table selection of excellent pictures. In character, it probably approaches most closely Kenneth Clark's *Civilisation*. To quote from the Introduction, the purpose in making the films was "to try and survey the whole animal kingdom and consider each great group of animals in the light of the part it has played in the long drama of life" and in order to do so on a practicable scale "to try and perceive the single most significant thread in the history of a group and then concentrate on tracing that, resolutely ignoring other issues . . .". To do so, one must know something about the anatomy and physiology of the basic design in each group—"The quintessence of, for example, a lizard is only fully understandable in the light of the particular possibilities and limitations dictated by its reptilian nature, and that, in turn, only becomes comprehensible in the light of its past."

David Attenborough has never recovered from his first experience of the tropics, and he is quite right not to; no one, including professionals, is really a biologist until he has experienced personally the incredible richness, the diversity, the multitudinosity of life where it really burgeons. And when he has, it is an experience he knows will be valuable to everyone, not only professionals, if it can be communicated. This book will be for very many people, especially young ones, literally an eye-opener on life; but it will be much more, because there is a definite theme, or rather several, running through it. It is the welcome antithesis to those woolly-mammal-pretty-girl books that bored everyone some years ago in the name of conservation.

It is based, therefore, as far as possible on living forms—indeed, one of the surprises of the television series is that while taking full account of time, and sufficient outstandingly well-preserved or interesting fossils, and of plate tectonics, it goes extremely lightly over our old friends the dinosaurs and other extinct reptiles, and most of the extinct mammals. For the purposes of

the book, this is probably right—far more can be said accurately of the anatomy, physiology and ecology of living things, and there is a rich array of 'living fossils' to draw on. Occasionally, this approach seems to bring a weakness of treatment; if one wishes to show the extraordinary continuity of groups, even among the vertebrates (which after all are a fairly compact group), then the beautiful sequence from early crossopterygians to early reptiles should surely not be omitted. To jump from lungfish and coelacanth to modern amphibians with only a passing mention of *Eryops* leaves one gasping in a very rarefied atmosphere. But a rigid exclusion was obviously necessary, and it is ungracious to pick out omissions.

One should be grateful, in fact, for how much there is in the book. Hardly any 'living fossil' of importance is omitted, and most get considerable discussion. (The only one I wished had not been left out is that tropical plant that so closely parallels the fossil land-plants (psilophytes) of the Rhynie Chert.) In each case, the present mode of life is discussed with expert knowledge and assistance. Every time, each group is related to the state of the Earth when it arose, the nature of the fauna and flora it had to live with, and what it did or does that others did not or could not do.

Inevitably there are many gaps in our knowledge, and the author is rightly insistent on them. Why do so many groups of invertebrates acquire fossilisable hard parts at the beginning of the Cambrian? Was it really a sudden cooling of climate that extinguished the large land-reptiles (and many small ones) at the end of the Mesozoic? What exactly is the evolutionary relationship between molluscs, arthropods and annelids? As against that, the author gives an excellent picture of life before the oxygen-shield developed, and living things could safely get out on to land. He points out the enormous advantages of being a reptile (you can live on one-fifth of the food necessary to keep an equivalent mammal stoked up), as well as the inevitable disadvantages.

All through, he avoids the fallacy of believing that a primitive form is necessarily inefficient; normally it is efficient enough for a particular mode of life. He is especially interesting in this connection on the marsupials, where, in fact, he seems to miss a point. The radiation of marsupials in South America in the Palaeocene seem to have taken place in the presence of eutherian mammals. So, far from being extinguished as more primitive and inefficient, they seized the ground insectivore, arboreal nocturnal insecti-

vore and carnivore modes of life so successfully that they held them to the exclusion of the South American eutherians. These took up all other possible modes, and the combined fauna did not become largely extinct until 50×10^6 yr later, when very different eutherians came in from the north and both marsupials and local eutherians suffered badly. Equally, there are numerous endemic eutherians in Australia today, coexisting with the marsupials and making up a complete range of fauna. With the ruin of their habitats by cultivation, both sorts become extinct.

Inevitably, some specialist will quarrel with almost any sentence of the book, but what is so useful is indeed the breadth of treatment and the insistence on living things as living things, solving particular problems of existence. Many of the points raised will stimulate naturalists to much further thought. It has been known for centuries that cormorants and darters get their plumage soaked under water, and have to sit out in the sun, drying themselves out. A survival of a primitive character? Possibly, but why should it survive? If every other sort of aquatic bird has evolved waterproof clothing, why can't they? But if, as suggested, the air trapped in this waterproof clothing makes the bird buoyant and it has to struggle to get down under water, does this mean that although cormorants and other pelecaniforms can stay under for only a short time, they are more adept in catching fast fish? If so, then the lack of air in the plumage may be a secondary adaptation, specially selected for. After a while, one begins to wonder if any character is merely primitive, merely there because one's ancestor had it. Is it not kept because it still has a use? The author comments on the retention by modern ratites (ostrich, emu, rhea, etc.) of adaptations for flight, such as air-sacs in the bones. Possibly when their ecology and physiology are better understood we shall see why they didn't convert their legs to horse-like ones. Whereas in the nineteenth century so much had to be explained away as the retention of ancestral characters, much now makes sense when we know how exactly an animal lives.

Coming to the book after the television programmes engenders mixed feelings. One is glad to have the book as a permanent record, and still more because it is extremely well written and enables one to grasp the themes of the whole series. The text is clear (I noted only four misprints—and one transposed caption); the price is low. The illustrations are superb, and only a very few are spectacular without much biological content (I noted the Goliath

Patterns in Crystals

by **N.F. Kennon**, *Dept. of Metallurgy, University of Wollongong, Australia*.

The book has been prepared for students of any age embarking on a study of crystals for the first time. It is appropriate for courses in crystallography, physics, chemistry, geology, mineralogy, ceramics, metallurgy, materials science and engineering at university, college, polytechnic or high school level. It is also particularly relevant to gemmology and lapidary hobby groups. The presentation is absolutely basic and directed to the reader seeking some understanding of the fundamental characteristics of a crystal and so learn the language that is used in the more advanced works.

Scattering of Light by Crystals

by **W. Hayes**, *University of Oxford*
and **R. Loudon**, *University of Essex*.

A description of phenomenon of inelastic light scattering by crystals and its use in obtaining information about the various kinds of solid-state excitation. The experimental techniques are largely common to the study of all types of excitation and the main components of light-scattering apparatus are described in detail. The properties of the excitations are derived in a general way, and experimental examples and simple theoretical interpretations are clearly presented.

Interpretation and Processing of Vibrational Spectra

by **M. Horak** and **A. Vitek**, both of the *Czechoslovak Academy of Sciences, Prague*.

This handbook contains a description of and methodological hints concerning basic procedures for the handling and interpretation of vibrational spectra. All commonly-used definitions, mathematical relationships, tables of constants, conversion factors and computation schemes for numerical treatment of experimental values have been collected. The book is supplemented with FORTRAN programs for the computer solution of many problems in molecular spectroscopy.

Organic Liquids: Structure, Dynamics and Chemical Properties

edited by **A.D. Buckingham**, *Cambridge University*,
E. Lippert, *Technische Universität, Berlin*
and **S. Bratos**, *Université Pierre et Marie Curie, Paris*.

This book is the first to be devoted to the theme of organic liquids. New physical techniques for studying the structure and properties of liquids are fully described and numerous applications of particular organic liquids presented. Emphasis is placed on the energetics and the dynamics of molecular interactions in organic liquids.

Organic Reaction Mechanisms 1977

edited by **A.C. Kripe** and **W.E. Watts**, both of the *School of Physical Sciences, New University of Ulster, Coleraine, Northern Ireland*.

The thirteenth volume, continuing the pattern now established for the series, surveys work on organic reaction mechanisms appearing in the literature dated December 1976 to November 1977. The aim, as before, has been to provide a concise and comprehensive coverage of work published in the period under review; where, at the time of writing, any particular results seemed of outstanding significance, these are described and discussed. The remainder are listed.

Soviet Scientific Reviews

a new series of authoritative annual reviews of Soviet science containing the most significant developments in physics, chemistry, astronomy, mathematical physics and biology—published under the auspices of the Academy of Sciences of the U.S.S.R.

edited by V.I. Goldenfeldt (Institute of Chemical Physics, Moscow), R.Z. Sagdeev (Institute for Cosmic Studies, Moscow), G. Friedlander (Brookhaven National Laboratory) and M. Livny (Université Pierre et Marie Curie, Paris)

Section B

CHEMISTRY REVIEWS—Volume 1 (1979)

edited by M.E. Vol'pin Institute of Organometallic Elements, Moscow

In this inaugural volume, two reviews deal with modern aspects of catalysis, one presents new achievements of a well-known Soviet school on reaction mechanisms involving organometallics, while the fourth paper is devoted to a rather new field of research—the effect of magnetic fields on chemical reactions.

The intention in this and subsequent volumes is to reflect the most important developments in chemistry in the U.S.S.R.

Contents: New Developments in the Reaction Mechanisms of Organometallic Compounds (I. P. Beletskiy); Molecular Bases for Heterogeneous Catalysts by Acids through the Participation of Brønsted Centers (V. B. Kuzinsky); The Effect of the Magnetic Field on Radical Reactions in Solutions (Yu. N. Molin, R. Z. Sagdeev and K. M. Salikhov); General Principles of Fermentation Catalysts (I. V. Berezin, A. A. Klyosov and K. Martinek)

Radiation Protection 1978

Published for the Commission of the European Communities, Directorate-General for Scientific and Technical Information and Information Management and EURATOM

A large amount of important fundamental research in radiation protection and allied subjects is sponsored by the Commission of the European Communities/EURATOM. This invaluable compendium is essentially a "who is doing what" compilation. Each research team head is asked annually to report on the work and progress of his team; this large publication is the result. Anyone engaged in research in the field of radiation protection will need this progress report to keep abreast of the considerable and varied amount of research work being done in Europe.

Sixth Symposium on Microdosimetry

Brussels, Belgium, May 1978

edited by J. Boaz and H.G. Ebert

Commission of the European Communities, Directorate-General for Research, Science and Education, Biology, Radiation Protection and Medical Research

The increasing use of nuclear energy and use of ionizing radiations and radioactive nuclides in medicine, industry, and research has resulted in an ever-growing potential hazard to man from radiation contamination. The determination of such hazards call for substantial efforts in microdosimetric and radiobiological research.

Contents include papers on: Biological and Chemical Effects of Radiation from External Sources and Incorporated Radionuclides (as interpreted with the aid of microdosimetry); Physical Principles of Radiation Interaction and Energy Deposition; Spatial and Temporal Distribution of Radiation Interaction Processes; Experimental and Mathematical Determination of Energy Deposition Spectra and Their Mean Values; Definition of Radiation Quality; Differentiation of Radiolytic and Nonradiolytic Radiation Mechanisms in Incorporated Radioactive Nuclides; Analysis and Interpretation of Dose-Effect Relationships; Models of Radiation Effect Mechanisms.

Darwin's legacy

C. M. Yonge

The Beagle Record: Selections from the Original Pictorial Records and Written Accounts of the Voyage of HMS Beagle. Edited by R. D. Keynes. Pp. 409. (Cambridge University Press: Cambridge, 1978.) £30.

HARDLY to be realised by that monarch or indeed by any of his subjects, yet—viewed in the light of what was to come from it—the voyage of *HMS Beagle* could well be considered the most momentous event during the short reign of William IV. That vessel departed on her circumnavigation of the globe 18 months after he came to the throne and returned less than a year before his death and the accession of Queen Victoria. The numbers of those aware of the course and significance of this voyage have recently been vastly increased following the broadcast of the imaginatively impressive television series by BBC-TV.

Putting aside for the moment the eventual consequence in *The Origin of Species*, there was early appreciation of the immediate achievements of the voyage. Darwin's original account of what he saw and did was initially somewhat hidden because it formed volume 3 of the *Narrative of the Surveying Voyages of HMS 'Adventure' and 'Beagle' between 1826 and 1836* published in 1839. This appeared before a wider public six years later as the *Journal of Researches into the Natural History and Geology of the Countries visited during the Voyage round the World of HMS 'Beagle' under the Command of Captain FitzRoy RN*, which a reviewer in the *Quarterly Review* was to describe as "One of the most interesting narratives of voyaging that it has fallen to our lot to take up, and one which will always occupy a distinguished place in the history of scientific navigation".

How fortunate it was, one may well reflect, that the prime concern of the

voyage was a survey of the southern shores of South America. As a naturalist attached to a naval vessel, Darwin might have gone to the Antarctic as Joseph Hooker did, to Australia and New Guinea as Huxley was to do, or perhaps not further than the eastern Mediterranean, the limit for Edward Forbes. But South America, not long freed from restrictions on scientific enquiry only penetrated by Humboldt, was a different proposition. To the prematurely judicious eye of Darwin, only 22 when the voyage began, this continent presented so very

however, with products of later years at Down House, would have been no more than the work of an outstanding naturalist had it not been for the publication of *The Origin of Species*. Darwin then changed the direction of human thought and based his demonstration of the fact of evolution on "certain facts in the distribution of organic beings inhabiting South America, and in the geological relations of the present to the past inhabitants of that continent". From that date all that Darwin had done and thought becomes of profound interest—above all his activities during the voyage of *HMS Beagle* which ended on November 7, 1836, "having completed the unusually long period of five years and one hundred and thirty six days" in commission.

Apart from the *Journal of Researches*, his granddaughter, Lady Barlow, edited *Charles Darwin's Diary of the voyage of HMS Beagle* in 1933 and twelve years later unpublished letters and notebooks in *Charles Darwin and the Voyage of the Beagle*, with

Two Fuegians fishing from a canoe

Drawing by Conrad Martens

many matters for contemplation—recent earth movements, a wealth of unusual animals and plants, above all of fossil remains—during the long process, with constant re-checking, of FitzRoy's surveys. There was the final bonus of the parting visit to the Galapagos Islands before the long journey home.

After return the first scientific outcome was *The Structure and Distribution of Coral Reefs*, the subsidence theory a result more of his previous observations of earth movements in South America than of those on the few coral formations encountered in the Pacific and Indian Oceans. All,

his letters to Henslow (1831–1860) in *Darwin and Henslow: The Growth of an Idea* in 1967.

The present, and most impressive, volume came initially into being—Professor Richard Darwin Keynes, a great grandson, informs us—after a chance encounter with Dr Armando Braun Menendez at Buenos Aires in 1968. His rich collection of books, charts and pictures dealing with the exploration of the southern hemisphere was found to include two of the sketch books of Conrad Martens. Darwin may introduce him; writing to his sister Caroline from Monte Video on November 13, 1833, with initial

reference to the first official artist, he states: "Poor Earl has never been well since leaving England and now his health is so entirely broken that he leaves us—& Mr Marten, a pupil of C. Fielding & excellent landscape drawer has joined us".

Such indeed were his qualifications as revealed by the great majority of the illustrations, many in colour, that adorn this book. They mainly depict scenes around the southern coasts because, after nine months, Martens left at Valparaiso, FitzRoy without money to employ him longer. But in these beautifully reproduced sketches of Port Desire, in the Beagle Channel, at the Santa Cruz River, at Chiloe and elsewhere, we view scenes that Darwin and all aboard HMS *Beagle* must have gazed upon. The few pictures not by Martens include John Gould's painting of *Rhea Darwinii* and FitzRoy's sketch of Coquimbo in Chile, with the simple drawing of Napoleon's tomb at St Helena by Darwin's servant Syms Covington.

The skilfully edited text, aiming at a general narration of events, is a judicious blend of extracts from the *Diary*, with all of Darwin's letters to his father and sisters, together with those, largely on scientific matters, to Henslow. FitzRoy is represented by extracts from the second volume of the *Narrative* with letters, both official and personal, to Captain Francis Beaufort, Hydrographer to the Navy and under whose instructions the voyage was carried out. There are concluding passages from the *Narrative* in which he defends the biblical story with the record of the rocks—potent evidence for evolution in Darwin's hand—all explained as a result of the flood!

Charles Darwin has been well served by his family—first by his sons, then by his granddaughter; and now a great grandson has produced the culminating tribute. □

Sir Maurice Yonge is Honorary Fellow in Zoology at the University of Edinburgh, UK.

Saga of a research vessel

George Deacon

On Almost Any Wind: The Saga of the Oceanographic Research Vessel "Atlantis". By S. Schlee. Pp301. (Cornell University Press: Ithaca and London, 1978.) £10.50.

THE *Atlantis* was built for the newly founded Woods Hole Oceanographic Institution in 1930–31, where, to begin with, most of the work was done in summer by scientists who held teaching appointments. Nevertheless the Trustees recognised that progress required a moderate sized ship, with reasonable living quarters, able to work in the deep oceans. H. B. Bigelow, Director of the Institution, and Columbus Iselin, general assistant and future master of the ship had much to do with her specification. She was a steel auxiliary, rigged as a ketch, with fore and aft sails, engined by a 280 hp diesel engine. Sail was chosen for economy, long range and steadiness, though it has often been suggested that yachtman's preference for sail had something to do with it. It was, perhaps, something of an anachronism from the start. UK oceanographers had proved Captain Scott's square-rigged, coal-fired *Discovery* unsuitable for making widespread observations in

reasonable time, and had replaced her by a fully-powered vessel built for the same price as the *Atlantis*, though costing twice as much to run. But the *Atlantis* proved ideally suited for pioneering work with new techniques and ideas, and it was not until post-War expansion, involving multi-ship operations, and widening international activities, extended and tightened the work load that "slogging across the ocean at a walking pace" proved unacceptable. As time went on she used her engine more and sailed less, till in 1960, when her tail-shaft broke—after post-war fitting of a more powerful engine—she had to call for a tug.

By 1935 she had greatly extended

our knowledge of the water circulation in the north-western Atlantic Ocean and Caribbean Sea, of daily plankton migrations, nutrient cycles, bacterial populations in sediments, the Gulf Stream, Sargasso weed, and CO₂ in atmosphere and ocean, among other basic problems. She went on to make extensive biological and physical studies of the Georges Bank area. She had also taken part in the development of a large quantitative plankton net with a triangular opening, with 50 ft sides, and the Leavitt release gear for opening as well as closing. She began seismic exploration at sea with Maurice Ewing "who was constantly banging on the Institution's door" and was used for development of more efficient core-samplers and the bathythermograph.

She was laid up when America joined the war, and afterwards used extensively in studies of underwater acoustics and underwater explosions. Her coverage was extended to the mid-Atlantic ridge, the Mediterranean Sea, the South Atlantic, the deep trench west of Chile and Peru, and to the Red Sea which proved a severe test of her suitability. There were fairly hectic times when she cooperated with the *Vema*, Ewing's own converted yacht which is still at work though without her rigging. Progress was most rapid when specialists of different kinds worked together. "Hersey's gang . . . charged across the frontiers of acoustic technique and instrumentation . . . like an institution within the Institution". Cooperative studies of the Gulf Stream were also very effective.

Schlee's book gives a lively and realistic account of life at sea in a small ship, based on the journals of her scientists and officers as well as the Institution's archives. She was often uncomfortable, "most of one's existence is passed exchanging one small discomfort for another". Shortage of funds was an obvious as well as concealed cause of trouble. She had a deep-sea winch from the start and a precision echo sounder in 1953, but no powered windlass or freshwater showers till 1954. She is not the only small ship in which continued discomfort has led to bother at sea and trouble in foreign ports, but she had her share.

In 1957 most of the trans-Atlantic sections were worked by a larger fully-powered ship the *Crawford*, soon joined by the *Chain*, and in 1963 by the *Atlantis II*. The old 'A-boat' was going down hill, but still used for tasks that she could do as well as and sometimes better than larger ships. In 1966 she was sold at a nominal charge to the National Council for Scientific Investigation in Argentina. She was re-

Courtesy Woods Hole Oceanographic Institution

fitted in Boston "such care had not been lavished on the vessel since the end of World War II".

When she entered Woods Hole for the last time all the town turned out to greet her. She could not have continued so long or done such good work if long-serving captains and crew had not taken continuing pride in her, their unusual spirit and enthusiasm more

than making up for her old-fashioned design. She is still working from Buenos Aires, mainly for training cruises.

Her fine story is well told. ☐

Sir George Deacon was Director of the former National Institute of Oceanography. He joined the RRS Discovery on 28 January, 1979, for further study of the Antarctic Ocean.

Varnished tale of Scripps

Edward Bullard

Scripps Institution of Oceanography: Probing the Oceans, 1936 to 1976. By E Noble Shor. Pp. 502. (Tofua Press: San Diego, California, 1978). Paperback \$5.95.

THE Scripps Institution of Oceanography was founded in 1903; in 1967 Helen Raitt and Beatrice Moulton published a history of its first fifty years. The present book starts in 1936, when Harald Sverdrup became Director, and brings the story up to 1976. It is a truly remarkable story. How did a small marine biological station grow to be the biggest oceanographic institute in the United States and, perhaps, in the world and then, in the 1960s, spawn a new campus of the University of California? The story is largely that of the three great Directors—Harald Sverdrup, Roger Revelle and Bill Nierenberg.

Sverdrup saw that the future of Scripps lay beyond the coastal waters of California. He obtained a ship, the beautiful schooner *E. W. Scripps*, built for racing and pleasure cruising, and converted her to a research vessel. It was Sverdrup who made Scripps a real oceanographic institute.

At the end of World War II he returned to Norway and, after a period of transition under Carl Eckart, Revelle became Director. Revelle had learnt during the War to 'think big'. He started a frantic race to raise money, hire people and build buildings. It was he who made Scripps larger and better and more fun than any other oceanographic institute. After a few years he grafted on to it a graduate school of science and engineering and turned this and Scripps into the University of California at San Diego, with himself as acting Chancellor. His strategy was original and brilliant. Most universities start with under-

graduate teaching and then, years later, develop a graduate school. This ensures a start with a rather pedestrian staff. Revelle's scheme enabled him to engage a prestigious staff from the start: among his early captures were Harold Urey and Maria and Joe Meyer. When the time came to choose a Chancellor for the new campus the Regents did not appoint Revelle. In 1964 he left California to become Director of the Population Studies Institute at Harvard.

It is a dramatic story and Betty Shor has told the part that concerns Scripps in meticulous and well documented detail; but somehow the realities of what happened have slipped away. Everything is so smooth, everyone behaves so well, everything succeeds, there are no rows and only the merest hint of the struggles that raged before Revelle was made Director and during his unsuccessful attempt to become Chancellor. We are told the names and deeds of all kinds of rather minor figures—for example, of the lady who presides so charmingly and efficiently over the aquarium bookstore—but the name of Edward Pauley who, as a Regent of the University, nearly wrecked the whole enterprise does not occur at all and, to come nearer home, no clue is given as to who at Scripps opposed Revelle's appointment as Director.

To be fair it must be said that Mrs Shor could hardly have told an unvarnished tale. She was asked by the Director to write the book and most of those mentioned in it are her friends. It would have been instructive to have reproduced some of the letters sent at that time to the President of the University and to see who said what and when; but it is clearly too much to expect.

After the turbulent reign and abdication of Revelle there was a short period during which Fred Spess was Director. He picked up the pieces, smoothed the ruffled tempers and continued the building programme; he then handed over to Bill Nierenberg. Nierenberg had the difficult and unenviable task of maintaining and expanding Scripps in a time when the country had lost its belief in the worthwhileness of anything. For a

Circle No. 68 on Reader Enquiry Card

while it looked as if Scripps would become 'Scripps rent-a-ship', an organisation that provided ships for anyone who could raise the money to run them. This has not happened; Scripps has remained what it was, an organisation practicing and encouraging all branches of oceanography; indeed it has taken on new responsibilities, such as the Deep-Sea Drilling Programme, and has built fine new buildings. Again the drama and the struggle are largely missing from the book. Again it all happens so smoothly and easily with no sense that but for Nierenberg, it might have come out very differently.

In reading the book one does learn a lot about what happened and about who did what and went where. There are accounts of projects and expeditions with well chosen extracts from letters, ships' logs and radio signals. The facts are set out with great care and detail. It is clearly a book that everyone interested in oceanography and in Scripps should read. It is not the ultimate book on the personalities and the period, but it is an essential contribution to the writing of such a book in 50 years time. ☐

Sir Edward Bullard is Emeritus Professor at the Scripps Institution of Oceanography, La Jolla, California.

Predator-prey interaction in arthropods

A. F. G. Dixon

The Dynamics of Arthropod Predator-Prey Systems. By M. P. Hassell. Pp. 237. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1978.) Hardback \$20; £10 70; paperback \$8 75; £4.40.

DR HASSELL has given us a lucid, clearly illustrated and eminently readable account of the development of analytical models of parasite-host interactions. This book is a most welcome exposition and summary of the current position in a rapidly developing aspect of ecology to which the author himself has been a major contributor.

Starting with the Nicholson and Bailey model the author develops step by step elegant analytical models framed in difference equations. This is achieved by the incorporation of more biologically significant parameters into the model. First, it is shown that stability can be predicted if an expression for density dependence is incorporated. A consideration of the functional responses of predators to prey density reveals the difficulties of extending relationships derived from studying mainly parasitoids. In true predators the search rate and handling time vary with stage of development of the predator and size of the prey, and this complexity poses difficulties in modelling this set of interactions. Consideration is given to the consequences of non-random search by a predator as opposed to the random search assumed by Nicholson and Bailey. More realistic prey and predator distributions tend to make the interaction very complex and difficult to explore analytically. However, the author shows that descriptive models have been useful in this context.

Next is revealed the powerful stabilising effect of mutual interference among searching parasites on parasite-host interactions, the constant area of discovery assumed by Nicholson and Bailey being a special case. However, although a widespread phenomenon in laboratory studies of parasite searching, it should be stressed that the extent to which mutual interference occurs in the field and the significance thereof still needs to be resolved. Many of the laboratory studies on mutual interference have been done at unrealistic densities. In considering the predator

rate of increase the author reveals another difference between predators and parasitoids. Prey density influences development, survival and fecundity in predators. If these factors are to be incorporated then the author suggests that we may have to abandon simple time dependent difference equations in favour of mathematically less tractable models.

Switching by predators from eating one prey species, to eating predominantly another species, as the proportion of the alternative prey increases, is shown to stabilise prey populations providing the predator population remains constant. Likewise, if switching is shown by the top predator in a community it can enable competing prey species to coexist. This is followed by a consideration of how it is possible for competing predators and hyperparasitoids to coexist.

The book ends with a most useful chapter on the theoretical basis for biological control which builds on the previous chapters. This reveals that an ideal parasitoid for use in biological control programme, all other things being equal, is one that has a high search rate and a marked ability to aggregate in areas of high host density; and it is argued that these are more likely to be attributes of specific rather than generalist parasitoids. However,

the case of the biological control of winter moth in Canada is used to show that when 'things are not equal' then predicting the outcome is difficult. Multiple introductions of parasitoids are shown now to be justified, as additional species will either coexist with the first species or replace it, and, whatever, the outcome, the equilibrium density of the host will fall.

The author justifies the book's title by regarding parasitoids as simple predators. He stresses that "true predator-prey models need to recover from the neglect at the hands of essentially parasitoid models". Only further study will reveal just how much of a special case the parasitoid-host interaction is and whether it can be usefully applied to the arthropod predator-prey system.

This book will undoubtedly be the standard text for both students and research workers in this field for some time to come. It is also a tribute to Nicholson and Bailey who, although unable to model the stability they observed in insect populations in the field, nevertheless produced a model which has been developed by the author and others to further our understanding greatly. At £4.40 the paperback version is excellent value. □

A. F. G. Dixon is Professor of Biology at the University of East Anglia, Norwich, UK.

Creative personality

Macdonald Critchley

Chase, Chance and Creativity: The Lucky Art of Novelty. By J. H. Austin. Pp. 237. (Columbia University Press: New York, and Guildford, UK, 1978.) \$16 20.

NOT for a long time have I enjoyed a technical apologia so much. Disjointed it may be, but the book is none the worse for that. Obviously the author is not only a biochemist of conspicuous ability, but he is something much greater, a thinker who writes well, and who is versed in the humanities. The book opens in a naive, autobiographical but intensely interesting fashion. We learn how as a junior hospital officer his interest was captured by a fascinating and argumentative case-conference between two of America's outstanding neurologists. His stint in the pathological laboratory was highlighted by the opportunity to study that rare and deadly disorder, metachromatic leuco-

dystrophy. He became intrigued by the presence of highly coloured urinary deposits which in an odd fashion changed in hue from reddish-purple to a vivid golden brown. What was their nature and what was the meaning of their metamorphosis? Patiently over the ensuing years Dr Austin pursued his quest, following one clue after another, communicating with other workers far and wide. Eventually he narrowed down the responsible factor to a deficiency in the enzyme sulphatase. This accomplishment led the author to investigate the nature of the Lafora deposits within the neurons in cases of myoclonus epilepsy. They proved to be comprised essentially of a glucose polymer. Important findings such as these inspired Dr Austin to extend his investigations into the chemistry of Alzheimer's disease and then the ageing of the brain.

This introduction leads on to sections 2 and 3, in which we are introduced to such fascinating topics as the nature of scientific discovery; the role played by mere lucky chance; the factor of intellectual preparedness; and the place occupied in research by serendipity. Concerning the latter, Dr Austin submits an allied but deviant conception which he calls "altamirage". This term was named after the "discovery"

REIDEL'S SPRING LIST

Interlinking of Computer Networks

KENNETH BEAUCHAMP (ed.)

Explores the technical, compatibility, and management problems that arise when linking computer networks to provide resource sharing over quite wide geographic distances. about 490 pp. Cloth Dfl. 80,— / US \$ 42.00 ISBN 90-277-0979-3

Dynamics of the Solar System

RAYNOR DUNCOMBE (ed.)

Papers based on I.A.U. Symposium No. 81. Covers all branches of research on solar system dynamics including investigations on the origin and evolution of comets. 381 pp. Cloth Dfl. 85,— / US \$ 44.50 ISBN 90-277-0976-9

KEEP OFF THE GRASS A Scientific Enquiry into the Biological Effect of Marijuana

GABRIEL G. NAHAS

At a time when strong forces in many communities are pressing for the legalization of marijuana, most public information on the subject concerns marijuana's impact from a legalistic rather than a scientific viewpoint. Professor Nahas' book presents the truth about many dangers of the drug from documented medical, pharmacological and scientific evidence, at a level which will be easily understood by those with little scientific background.

Water Flow In Plants

J.A. Millburn

This book explains in a unique, non-technical manner how plants have become adapted to exploit the unusual properties of water. The text is designed to operate at two levels. In its simplest form it offers a clear introduction to plant function and structure in descriptive terms; at a more advanced level it deals with quantitative aspects of the work, and encourages the reader to use the equations, data from tables and the numerous appendices. The book will be a useful guide to undergraduate and graduate students of biology and botany, to teachers of plant physiology, and to postgraduates beginning work in this field. Paper 0 582 44387 3 £6.75 net

Cell Motility

H. Stebbings and J. S. Hyams

Since the introduction of the first microscopes, scientists have been fascinated by the movements of cells. Once a purely descriptive science, the study of cell motility has advanced rapidly in recent years to become one of the most productive experimental areas of modern cell biology. This is the first text of this length to be devoted to the subject. Clearly written and well illustrated, it will be invaluable to senior undergraduates of biology, botany and zoology, as well as to lecturers in cell biology. Paper 0 582 44380 6 £4.50 net

Fisheries Ecology of Floodplain Rivers

R.L. Welcomme

This book assembles information on the general ecology of those rivers that undergo seasonal flooding, and applies it to the special case of fisheries. It shows how the various activities occurring in river basins can influence the fish communities inhabiting them. The book will be invaluable to freshwater and fisheries scientists, and will also interest ecologists, students, and the more general reader concerned with environmental problems. Paper 0 582 46310 6 £19.95 net

The Hypercycle

A Principle of Natural Self-Organization

The Darwinian evolution of the species was, in all likelihood, preceded by an analogous stepwise process of molecular evolution. This hypothesis, developed by Nobel prize winner, Prof. Manfred Eigen and the renowned theoretical chemist, Prof. Peter Schuster, is presented here for the first time in book form. The authors suggest that hypercyclic organization led to a unique cell machinery operating by means of universal code. Originating in a molecular quasi-species, the hypercycle evolves by mutation and gene duplication into more complex forms.

Written with chemists, biochemists, biologists and physicists in mind, this book provides a deeper understanding of the origin and evolution of life, and will furnish the basis for many new experiments.

of the prehistoric art within the caves at Altamira by Don Marcelino—more particularly by his dog, and especially by Maria, his 9-year-old daughter. It was this little girl who was the first to direct her gaze upwards, and thus become the discoverer of the glories of the "Sistine Chapel of prehistory". Altamirage is defined as "the facility for encountering unexpected good luck as the result of highly individualised action". It transcends the boundaries of serendipity in its role of personal action in chance.

The erudite and stimulating chapters which make up the final sections are psychological and philosophical in nature, and deal with such subjects as, for example, the creative personality. In an interesting fashion the author reviews the considerable literature concerning the anatomy of creativity. He emphasises, in a manner which merits the attention of all senior academics who dispense power and patronage, Dragstedt's essay "Who Killed Cock Robin" in which is described the gradual death of creativity in a researcher who becomes enmeshed in too many committees. In Dragstedt's words, "the early days in the laboratory are the golden years for many scientists. After he becomes known, the volume of mail, telephone calls, number of visitors, organisational activities, including committees by the dozen, and demands for lectures, reviews and community activities grow insidiously and will destroy the creativity of the scientist if unopposed".

Throughout his book Dr Austin recurrently mentions the part which the arts may have contributed to his scientific career. Music is there, and more particularly an almost obsessional, lifelong preoccupation with colour. It is tempting to believe that the author is, or was, a synaesthetic thinker, though he nowhere explicitly says so. Likewise he speaks of a reality familiar to some who have closely studied the phenomena of the body-image, and which the reviewer has never before seen expressed in print. According to Austin, "Even now, writing these lines, I retain a clear visual image of the scene at the desk where these ideas burst forth. This time, in a kind of mental double vision, I am both a participant in the process and a spectator hovering over a point about five feet up and ten feet directly to the rear." (My italics.)

The reviewer has nothing but admiration for *Chase, Chance and Creativity*, and confesses that Dr Austin is a man he would very much like to congratulate in person. □

Macdonald Critchley is Honorary Consulting Physician at the National Hospital, London, UK.

Major flowering plant families

Peter D. Moore

Flowering Plants of the World. Edited by V. H. Heywood. Pp. 335. (Oxford University Press: Oxford and London, 1978.) £7.95.

It is an unusual experience to come across a book which demands unreserved praise; this one does. In both concept and execution this work is eminently laudable. It aims at providing a simple introduction to the major flowering plant families of the world; over 300 are described, so it approaches a comprehensive coverage.

The book commences with a brief introduction to the structure and biology of the angiosperms together with an outline of their evolutionary history and the criteria which are used in their classification. As the book is likely to attract a wide market outside the circles of academic botany, this is a very necessary section. Even within such circles it will prove a useful summary for students. It includes Stebbins' diagrammatic portrayal of evolutionary relationships within the flowering plants.

There follows a synopsis of classification in which families are arranged into their ten Orders. On the whole the Stebbins system is used, except where some small families are fused with closely related ones.

Technical terminology in plant morphology is, according to Heywood, one of the major obstacles for the amateur, which keeps him from the appreciation of much taxonomic botany. Undoubtedly he is right in this, and the provision of an illustrated glossary should go a long way towards demolishing this obstacle, especially as the attractiveness and clarity of the illustrations make it quite the most explicit glossary of its kind currently available.

The bulk of the text (300 pages) consists of a systematic treatment of the plant families. The description of each family includes an assessment of its distribution, both verbally and cartographically. The distribution maps are a unique feature of the book, which will prove particularly interesting to those interested in phytogeography. The verbal descriptions are necessary supplements; for example, although the family Magnoliaceae is

found in southeast Asia and in North, Central and South America, 80% of the genera come from the former region. A map on its own could be misleading.

The diagnostic features of each family are then described, and here the use of technical terms for the sake of brevity will necessitate frequent use of the glossary. Major subdivisions within the family are then described and finally its economic value is considered. The latter is a source of much interesting information and includes medicinal, timber and horticultural uses.

Quite the most striking features of the book are the illustrations. Each family has a few characteristic members illustrated both by habit drawings and flower sections. Many of the illustrations are reproduced in a sepia monotone with certain parts, often the flower or fruit, picked out in full colour. It is impossible to convey in words how aesthetically pleasing and technically informative this form of representation has proved. It combines the clarity of a line diagram with the naturalness of a well-composed painting. Victoria Goaman, Judith Dunkley and Christabel King, together with the publishers, must be congratulated on a set of illustrations which are unsurpassed in current popular botanical literature.

It would be petty to dwell upon errors in the text; they are present, but fortunately scarce. For example, the primrose is referred to as *Primula veris* rather than *P. vulgaris*.

There are no comparable books which could compete with this one, either in quality of production or in price (at under £8 it must be rated a bargain). Older books, such as G. H. W. Lawrence's *Taxonomy of Vascular Plants* (Macmillan, New York, 1951), which have served generations of students, lack the fine illustrations and the distribution maps of Heywood's book. These features will also appeal to the very considerable amateur market in both Europe and North America.

This book is more than a textbook of taxonomy, it is a publication which will stimulate an interest in plants within any who open its covers. It is an item which all biologists should have on their bookshelves. Oxford University Press are to be congratulated on the production of a book which will be of great service to botany and which is a credit to British publishing. □

Peter D. Moore is Senior Lecturer in Plant Sciences at King's College, University of London, UK.

Occasions of experience

Eric Ashby

The Star Thrower. By L. Eiseley. Introduction by W. H. Auden. Pp. 319. (Wildwood House: London, 1979.) £5.95.

THIS book is about Nature but it is an unusual book to be reviewed in *Nature*. Its author was a professor of anthropology but the book would score zero in an examination paper in anthropology. It is about Man in the Darwinian scheme of evolution but it is concerned with "the phase beyond the evolutionist's meager concentration upon survival".

Loren Eiseley was a poet who became a professional scientist. The essays and poems in this volume were collected for publication shortly before his death in 1977. They are autobiographical musings written by a deeply sensitive man who never reconciled himself with what he calls the "crystalline and icy objectivity" of the scientific attitude towards Nature. The imagery is vivid and personal; the style ornate, and in places opaque. His naturalist's eye observes something—a playful fox cub too young to know fear, a spider keeping its web under surveillance, a fossil bone, a flint arrow head—these ignite his imagination and illuminate Man's relationship with the other living things around him.

The most interesting essays are those on science and humanism. Eiseley is distressed by reductionism. He does not dispute the need to think about living things at the level of atoms and molecules but he asserts that the things worth understanding about Nature cannot be discovered at this level; which of course raises the question: What, then, does he think is worth understanding? He answers this question by drawing the reader away from Darwin to Emerson and Thoreau. It is the numinous in Nature which matters to Eiseley, the attitude which the Germans call *Ehrfurcht*, the eye that sees the whole. "The finest intellect", he writes, "is that which employs an invisible web of gossamer running into the past as well as across the minds of living men and which constantly responds to the vibrations transmitted through these tenuous lines of sympathy".

Eiseley is not the only scientist who recognises the limits of reductionism and the dilemma of a theory of evolution from which the idea of purpose has been excluded. But, for my part, I do not think an appeal to the heady

prose of Emerson or the (sometimes querulous) protestations of Thoreau is likely to clarify these issues. Two essays on Thoreau—by far the best in the book—raise an interesting question, namely: What is the difference between imagination as it is used in science and imagination as it is used in poetry? Unfortunately Eiseley misses the opportunity to discuss this question. Imagination is as important in science as it is in poetry. The difference in the use made of imagination is this: the scientist disciplines imagination to make it comply with observation or experiment; the poet gives imagination free rein to range over whatever imagery his mind can design. Both these uses of imagination are legitimate. But it is confusing to mix the usage, and that—so it seems to me—is what Eiseley frequently does.

The Star Thrower has earned eulogies from other reviewers. I confess that I find the book disappointing. I think the reason for my disappointment is the use Eiseley makes of imagination. He uses it as a poet does, displacing (as he says of Emerson) "the sedate white doorstone into nature by something wild and moon-haunted, whether in science or art." In art, yes; Wordsworth, Emerson, Walt Whitman have

put on record vividly the human response to Nature. But in science, moon-haunted descriptions are not satisfactory records of Nature. Eiseley has tried to do something very important: to describe the intricacies of the biosphere as compellingly as Watson and Crick describe the intricacies of the double helix. It is an immensely difficult task and to have tried and failed is in itself creditable. Some poets—Robert Bridges in the *Testament of Beauty*, for instance—have got closer to it. So have some essayists—Lewis Thomas, for instance, in his charmingly allusive *Lives of a Cell*. I think the prize goes to A. N. Whitehead (and Eiseley generously acknowledges this), for he set out, with impeccable logic, the concept of process in evolution in a way which does enable one to think about the biosphere with the clarity Eiseley was seeking. It was Whitehead who linked together what he called "occasions of experience" like bars of music in a sonata. Eiseley's book, too, is a record of occasions of experience. It is not a clear record, but it is the testimony of a sincere and sensitive poet. □

Belief in a created Universe

P. E. Hodgson

The Road of Science and the Ways to God. By S. L. Jaki. Pp. 478. (Chicago University Press: Chicago; Scottish Academic Press: Edinburgh, 1978.) £9.50.

PROFESSOR JAKI is already well known as an historian of astronomy, with major works on the Milky Way, Olbers' Paradox and the Planetary System. In his *Relevance of Physics* he reviewed the history of physics and its relationship to other disciplines, and in *Science and Creation* (for review, see *Nature* 251, 747, 1974) he showed why science had its only viable birth in seventeenth-century Europe and not in the civilisations of antiquity. In the present volume, containing his Gifford Lectures for 1975 and 1976, he extends this line of thought by showing the deep connection between scientific creativity and natural theology. His thesis is that the belief in a created Universe implies the

epistemology that underlies scientific creativity, so that the road of scientific development and the ways leading the mind from the created world to a knowledge of the Creator are mutually sustaining and inextricably intertwined.

Science first came to maturity when Newton found the middle way between the empiricism of Bacon and the rationalism of Descartes. Newton's mind was dominated by a vision of truth incarnate in nature, a truth that can be revealed by a dynamic interaction between bold speculation and meticulous experimentation. His theory of gravitation was a creation of the mind—a leap beyond sensory data—but because it was a vision rooted in the data provided by nature it could become a vigorous science. Newton's awareness of the created nature of the world implied a recognition of its contingency, and hence the necessity of painstaking experimental work to uncover its secrets. The middle way found by Newton thus transcended empiricism without becoming trapped in a *priorism*.

The reverse side of this thesis is illustrated by detailed discussions of subsequent philosophers including Hume, Locke, Kant, Fichte, Hegel, Schelling, Mill, Comte and Mach. Their admiration of Newton's achievement and their ambitions to extend his

ELECTRON MICROSCOPY IN HUMAN MEDICINE

Edited by **JAN VINCENTS JOHANNESSEN, M.D.**, Consultant Pathologist and Head of the Laboratory of Ultrastructural and Experimental Pathology, Norwegian Radium Hospital; and **Norsk Hydro's Institute for Cancer Research**

This wide-ranging but intensive reference series is a convenient aid for education, routine lab work, and research in histopathology, virology, microbiology, and other clinical specialties. By demonstrating the ultra-structural aspects of disease, it will help to stimulate the search for new diagnostic and therapeutic methods.

■ **VOLUME 1: INSTRUMENTATION TECHNIQUES** Transmission and scanning electron microscopy, fixation, embedding, staining, special stains for semithin sections, negative staining, cryo-sectioning, freeze-etching, electron probe X-ray analysis, stereology, histochemistry, autoradiography, paraffin, photography, the electron microscope, and occupational hazards. (0-07-032501-4) 1978, 348 pages, \$56.00

■ **VOLUME 2: CELLULAR PATHOBIOLOGY, METABOLIC AND STORAGE DISEASES** Cell and tissue structure and function, injury reactions, lysosomal disorders. (0-07-032502-2) 1978, 256 pages, \$34.50

■ **VOLUME 3: INFECTIOUS AGENTS** Viruses, bacteriophages, mycoplasma agents, bacteria, protozoa, and fungi. (0-07-032503-0) May 1979, 276 pages, \$45.00

■ **VOLUME 4: SOFT TISSUES, BONES AND JOINTS** Degenerative and inflammatory disorders, tumors, tumor-like conditions, soft tissue tumors, striated muscles. (0-07-032504-9) May 1979, 275 pages, \$45.00

■ **VOLUME 5: CARDIOVASCULAR SYSTEM, LYMPHORETICULAR AND HEMATOPOIETIC SYSTEM, RESPIRATORY TRACT** Heart, blood and lymph vessels, thymus, bone marrow, blood, lymph nodes, and spleen. (0-07-032505-7) July 1979, 274 pages, \$45.00

■ **VOLUME 6: NERVOUS SYSTEM SENSORY ORGANS, SKELETAL MUSCLE** Metabolic and demyelinating conditions, viral diseases and tumors of central nervous system, peripheral nerves, eye, inner ear, and respiratory tract. (0-07-032506-5) August 1979, 278 pages, \$45.00

■ **VOLUME 7: DIGESTIVE SYSTEM** Oral cavity, salivary glands, gastrointestinal tract, and exocrine pancreas. (0-07-032507-3) July 1979, 272 pages, \$45.00

■ **VOLUME 8: THE LIVER, THE GALLBLADDER, AND BILIARY DUCTS** Normal and pathological ultra-structure of liver parenchyma and biliary tract. (0-07-032499-9) April 1979, 224 pages, \$48.00

■ **VOLUME 9: UROGENITAL SYSTEM, PLACENTA, AND BREAST** Kidney, lower urinary tract, male genitalia, spermatozoa, female genital tract, placenta, ovary, and mammary gland. (0-07-032508-1) June 1979, 396 pages, \$54.00

■ **VOLUME 10: ENDOCRINE ORGANS, SKIN** Pituitary, thyroid, parathyroids, adrenals, and endocrine pancreas. (0-07-032509-X) October 1979, 280 pages, \$45.00

■ **VOLUME 11: SPECIAL APPLICATIONS AND FUTURE TRENDS** Advanced techniques such as fixation procedures, scanning electron microscopy, stereology, electron microscopy of molecules, and forensic medicine as well as some views on the future role of electron microscopy in human medicine. (0-07-032510-3) October 1979, 268 pages, \$45.00

To order all eleven volumes, place your order for the entire set (0-07-079276-3: \$494.00) Single volumes will be shipped individually to you as they are published.

SPECIAL ANNOUNCEMENT OF A NEW QUARTERLY

The new *Journal of Ultrastructural Pathology* is scheduled to begin publication in late autumn of 1979. Focusing primarily on human pathology, this journal will publish articles on cell biology, case histories, reviews of new instrumentation and techniques and book reviews. For instructions on the submission of articles for possible publication, write to the editors: **Jan Vincents Johannessen**, Dept. of Pathology, Norwegian Radium Hospital, Oslo 3 Norway or **Victor E. Gould**, Dept. of Pathology, Rush Medical College, Chicago, Illinois 60612 U.S.A.

For subscription information, contact **Suzanne E. Heyl**, Hemisphere Pub. Co., 19 West 44th St., New York, N.Y. 10036 U.S.A.

Also Available from McGraw-Hill—

■ **LABELLED ANTIBODIES IN BIOLOGY AND MEDICINE** by **Aurel Feteanu**, U. of Bucharest. Details the apparatus, solutions, buffers, and techniques needed to obtain, isolate, and purify antibodies for labelling. Also describes methods using fluorochromes, radioactive isotopes, ferritin, and enzymes while explaining their medical applications. Includes 360 photos — over 200 in full color. (0-07-020643-0) 1978, 410 pages, \$39.50

■ **PRINCIPLES OF BIOCHEMISTRY, SIXTH EDITION** by **Abraham White**, Distinguished Scientist, Syntex Research and Stanford U. Sch. of Med.; **Philip Handler**, President, National Academy of Sciences and Prof., Duke U. Sch. of Med.; **Emil L. Smith**, Chairman of Dept. of Biological Chemistry, UCLA Sch. of Med.; **Robert L. Hill**, Chairman of Dept. of Biochemistry, Duke U. Sch. of Med.; and **I. Robert Lehman**, Chairman of Dept. of Biochemistry, Stanford U. Sch. of Med. Gives massive coverage of sweeping new discoveries made since 1972, and concentrates throughout on medical aspects with new data on blood composition, plasma, clotting, hemoglobin and leukocyte structure and function, insulin, genetics, electrolytes, and hormones. Includes five brand new chapters on prostaglandins, viruses, immunoglobulins, complement, and the role of the thymus. (0-07-069759-0) 1978, 1492 pages, \$35.00

■ **THE METABOLIC BASIS OF INHERITED DISEASE, FOURTH EDITION** Edited by **John B. Stanbury**, Director of Dept. of Nutrition and Food Technology, MIT; **James B. Wyngaarden**, Chairman of Dept. of Medicine, Duke U. Sch. of Med.; and **Donald S. Fredrickson**, Director of National Institutes of Health. For each of hundreds of disorders, gives full data on known physiology, pathology, biochemistry, genetics, metabolism, inheritance patterns, and therapies, thereby helping to trace clinical symptoms directly to altered metabolic pathways. Covers newly discovered disorders and variants of well-established syndromes, and presents thousands of valuable references to original research. (0-07-060725-7) 1978, 1755 pages, \$65.00

All prices quoted in U.S. dollars and subject to change without notice.

Principles of Biochemistry, 6/E and **The Metabolic Basis of Inherited Disease, 4/E** available from McGraw-Hill in U.S. only. All other titles available through your usual supplier, from your local McGraw-Hill representative or office, or from **Lenore Stanoch/Room 3064-73**, McGraw-Hill International Book Company, 1221 Avenue of the Americas, New York, N.Y. 10020, U.S.A.

'AnalaR' Standards for Laboratory Chemicals

The registered trade name 'AnalaR', first used in 1934 to designate analytical reagents conforming to published specifications and of British origin, is now recognised internationally as being synonymous with purity and reliability.

'AnalaR Standards for Laboratory Chemicals' published by AnalaR Standards Ltd is regarded as the definitive work on analytical reagents and methods of test.

The new edition, the seventh, describes in detail the tests applied to some 340 reagents and the specification to which each guaranteed 'AnalaR' product must conform.

Reflecting the recent advances in analytical chemistry, the volume is an invaluable reference and can only be obtained from the licencees of AnalaR Standards Ltd.

method far beyond physics was seldom matched by any comparable understanding of his scientific work, still less of its epistemological roots. Insofar as they departed from the epistemology inherent in the ways to God, they developed theories of science that would have been lethal if scientists had taken any notice of them. Fortunately they did not, so no great harm was done, at least to science itself.

The second great period of scientific creativity was initiated by Einstein and Planck, and here again the wellsprings may be traced to the same theistic source. Although initially Einstein was influenced by Mach, his scientific creativity gradually forced him to repudiate Mach's sensationalism. Its ravages are still evident in the philosophy of quantum mechanics and in Bohr's theory of complementarity.

Fragmentation of culture

W. H. Brock

Nature and the Victorian Imagination. Edited by U. C. Knoepfelmacher and G. B. Tennyson Pp. 519. (University of California Press: Berkeley, Los Angeles and London, 1978.) £15.

"WHAT a glorious title, *Nature*, a veritable stroke of genius to have hit upon", wrote the mathematician J. J. Sylvester enthusiastically to *Nature's* editor, the astronomer J. N. Lockyer, on the first appearance of the journal in November, 1869. Yet, although the title was copied by French, Italian, Dutch and Norwegian commercial science publications, it is significant that when American scientists founded a similar journal in 1883 they chose the title *Science*. Again, T. H. Huxley, in translating a German nature poem for the first issue of *Nature*, could think of no more fitting a preface for a periodical "which aims to mirror the progress of that fashioning by nature of a picture of herself, in the mind of man, which we call the progress of science". Yet, as the editors of this elegant book point out, by 1918 any serious writer, painter or scientist would have thought it "impossible, quaint, archaic, Victorian . . . to rise from a bird's plumage to a consideration of man's position in the Universe".

That the scientific community pioneered this "denaturing" process few would deny. Put briefly, the collective theme of this interdisciplinary feast of a book is what S. F. Cannon has called "the fragmentation of culture", whereby the common

At the present time, increasing evidence of the singularity of the Universe is again pointing to its radical contingency.

Professor Jaki develops his theme with a masterly command of the original sources, and the text is supported by over a hundred pages of notes and references. It is so densely packed with ideas that it is not easy to read, but scientists, philosophers and theologians will find it a mine of stimulating analysis. Inevitably his thesis raises many other questions such as the relationships between the Christian churches and science, which have not always been harmonious, and the acceptance of science by radically different cultures; and these are apt future subjects for Jaki's pen. □

P. E. Hodgson is Lecturer in Nuclear Physics at the University of Oxford, UK.

religious, moral, poetic and scientific perspective of the early Victorians was gradually fragmented into, on the one hand, a literary consciousness which continued for a long time to seek symbols in Nature; and on the other, the various scientific forms of imagination which pursued separate, and sometimes, unrelated, disciplinary goals by measurement, experiment and abstraction. That "Ruskin . . . in looking at botanical specimens . . . saw nothing of what Darwin saw in them", is, for example, brought out by F. Kirchoff in a fascinating analysis of Ruskin's floral mythology in *Proserpina*.

Apart from R. Smith's fine essay on the human significance of biology, the question whether value systems were completely abandoned by scientists is, unfortunately, little explored by the 26 contributors to this volume, which is primarily addressed to the literary reader. Concentrating on the changing artistic interpretation of Nature, there are only three essays by historians of science who actually explore the directions taken by chemists, physicists and biologists during the century. These, together with a fine essay on science education from the Arnold scholar, R. H. Super, stand for the systems of knowledge that challenged traditional "inscape". Ignored, except for the editors' allusion to the nature writer, W. H. Hudson, is the powerful tradition of natural history (whose social history has been so ably analysed by D. E. Allen in *The Naturalist in Britain* (Allen Lane: London, 1976) which may well be seen as continuing a moralistic science long after Darwin. By the same token, the essays are exclusively concerned with the intellectuals' imagination; whereas cursory reading of "working-class" natural history journals suggests that their readers continued, like the literary

PUBLIC POLICY AND THE DIFFUSION OF TECHNOLOGY

An International Comparison of Large Fossil-Fueled Generating Units

by J. DeYoung & J. Tilton

This study investigates the adoption of new technology in the electric utility industry. It examines the rate at which the large-scale generating units have been introduced, and considers how public policy can influence this growth. Diffusion is investigated in three countries — the U.S., Canada, and Britain — focusing on the last quarter century.

and artistic intelligentsia (but unlike laboratory-bound biologists) to find mystery and feeling in Nature.

Despite such reservations the book triumphantly succeeds in revealing the many-sided character of the Victorian imagination as it responded to Nature. The essays include a photographic study of how the Victorians perceived nature through the camera lens; several interesting treatments of the ways in which natural space was tamed symbolically in architecture and domestic ornamentation; how the Victorians explored wild and mysterious environments like the Alps and subjugated them by sports and tourism; how their painters were torn between moral and realist models of representation (a notable essay here on the rainbow by G. P. Landow); and how the issues were perceived by such sages as Keble, Dickens, Browning, Mill and Hardy. Printer, publisher and editors are to be commended for placing footnotes where they belong, and for their choice of quality illustrations and fine typography. They have produced a book which is not only a pleasure to read, but also to hold, handle and shelf. □

Studies in Biology

— new titles

107 Pollen and Allergy

R. Bruce Knox

This book provides an introduction to the life of the pollen grain and, in particular, deals with its dual role in plant fertilization and human allergic disease.

Paper £1 75

108 Animals Under Stress

John Archer

This book introduces the reader to the various aspects of research on stress, drawing on material from a number of academic subjects including experimental psychology, physiology, ethnology, ecology and evolutionary biology.

Paper £1 70

For publication in June

109 Lizards — A Study in Thermoregulation

R. A. Avery

This book gives an account of some aspects of the ecology, behaviour and physiology of lizards, and shows how all of these can be interpreted from an understanding of the ways in which the animals use sunshine and other sources of heat in order to regulate their body temperature

Paper £1.80

110 Sexual Incompatibility in Plants

Dan Lewis FRS

Many plants have evolved genetical-biochemical methods of self-incompatibility to control effectively self-pollination, a type of inbreeding which, because of the extremely narrow distribution of pollen and seeds, is of considerable evolutionary importance since it discourages any further diversification

Paper £1 90

'The series provides a medium by which biologists can be kept up to date with developments in specific areas of biology. They are reasonably priced and are an ideal way by which individuals, schools, colleges and universities can supplement their libraries in particular fields' — *Nature*

Edward Arnold

Empirical, useful, predictive enterprise

J. Z. Young

Reliable Knowledge: An Exploration of the Grounds for Belief in Science.

By J. Ziman. Pp. 197 (Cambridge University Press: Cambridge, 1978) £7 95

PROFESSOR ZIMAN is a mathematical physicist but in this book he has devoted himself to the task of trying to define the aims and methods of all science. Wisely he begins with his own subject and bravely he goes on to extend his thoughts to biology and even sociology. Probably each scientist will like best the parts of the book that deal with subjects other than his own. But this is not to say that any of it is superficial or inaccurate, at least so far as my limited knowledge goes. Quite the contrary, he has succeeded in distilling the essence both of the results and limitations of very wide areas of science.

His general thesis is that "*the goal of science is a consensus of rational opinion over the widest possible field*" (p3) (italics throughout are his own). This is achieved, because of the very specific "internal sociology" of the scientific communities, which allows for the communication of what he calls "consensual knowledge". The definition of this is that it is unambiguous and agreed to be true by all participants. The ideal form of it is mathematics and Professor Ziman takes a lot of trouble to explain how this approaches an ideal language. It is refreshing to find that he is under no illusions that it is perfect: "Unfortunately deficiencies of consensibility can be found even in the most sophisticated mathematical systems". In particular he emphasises that "the hope of finding a unique and perfectly logical language of this kind is vain". In order for scientists to agree, they have to share certain fundamental beliefs, for example, in the Kantian categories of space and substance. He is unwilling at first to define and delimit the range of these "supreme principles". As his exposition proceeds it becomes clear that he believes that they depend upon certain innate human capacities, especially "the mysterious skill that we call pattern recognition". Moreover,

this is not amenable to complete logical analysis and is not even completely uniform amongst all men.

Having thus warned us that mathematics is not a perfect tool he nevertheless believes it to be the best available and proceeds to give an excellent account of how it functions. His beautiful description of the diverse powers of synthetic and analytical methods is presumably elementary for the mathematician but simple and direct for the rest of us; and done almost without abstract symbols. He follows it through to discussion of the place of experiment and of models and hypotheses. Popper's criterion of falsifiability he holds to be "strategically sound but tactically indefensible", a polite way of saying that it is no use. Here, as very often, he speaks of the scientist actually at work, a rare virtue in a theoretician. Every theory can be falsified by some of the observations, the question is whether it is the best available; and he illustrates this by the controversy over the missing solar neutrinos, which are much less numerous than theory predicts. He rightly contrasts the "calm order and perfection of well established theories" with the "controversy, conjecture, contradiction and confusion" of the frontline of research.

His determination to show science as it really is leads him next to discuss the principles of observation and particularly pattern recognition. "The assumption that *all observers are equivalent*" is not merely a basic principle of Einstein's theory of special relativity; it is the foundation stone of all science. However, obvious though this seems, it in fact implies that "scientific knowledge cannot be justified or validated by logic alone". As observers differ, "statements about the real world are always subject to uncertainty. They cannot all be given precise status—'true' or 'false'—their logic is *three-valued*, falling into the categories 'true', 'false' and 'undecided'." Ziman gives much discussion of the implications of this thesis which, as he says, may not be of great importance in physical science but imposes limits in biology and especially in sociology. In particular he emphasises the great influence of the sociology of belief in determining the observations that are made. Every scientist must use the paradigms of his age and Ziman gives examples of how they determine the observations he makes and the interpretations that he puts upon them.

So much cautious scepticism might well lead to scientific pessimism. But Ziman is much too practical to be a defeatist. Whatever the fundamental

Spring is Sprung

Time for Spring Cleaning

Don't forget those bookshelves. Delve out the dust, fish those history volumes out of the gardening section, throw away those tatty yellowing paperbacks. Make room for some clean, bright, up-to-date reading. Try some of these, from HMSO, for a start. Guaranteed to spring-clean your winter-tired brain.

South Downs Way

Latest in HMSO's superbly produced Long-distance Footpath Guides. Large-scale, page-size Ordnance map sections complement lively text and clear directions for marvellous walks over the famous Seven Sisters cliffs and Beachy Head, into the Sussex countryside. ISBN 0 11 700840 0 210mm 126pp £2.95 (£3.13½). (Send for FREE brochure on all of Britain's Long-distance routes, from the Scottish Border to Wales and Cornwall. (Address as for Bookshelf))

Thomas Bewick Wood Engravings

The most enchanting little book we have seen for a long time. Brief biography of a man who clung to his native Tyneside as Constable clung to Suffolk, yet produced the liveliest and most imaginative of nature studies. Some from places around him — cats, cows, farm scenes — others from vivid imagination — peacocks, giraffes, all manner of creatures he never actually saw. Enchanting to the eye, and a refreshing read for springtime.

ISBN 0 11 290290 1 186mm 32pp £1 (£1.12)

The Handwriting of Joseph Banks

The Handwriting of Joseph Banks, his Scientific Staff and Amanuenses

is a study of historic handwriting from the Natural History Museum. Banks, after voyaging with Captain Cook, became the acknowledged expert on botany of the Antipodes and tropics. Most of his sheets of specimens are now in this Museum. Some were written up by himself, others by a retinue of assistants. Until recently it has been difficult to establish who labelled what. This new study unravels a natural history mystery. ISBN 0 11 982778 6 245mm 86pp £9.50 (£9.68½)

A Course in Elementary Meteorology

requires only modest knowledge of physics, approximating to O-levels. Modern research and older ideas are combined, and there is far more explanation than in most elementary textbooks. Yet the usual extensive mathematics are avoided. Spring is sprung, but will the sunshine last? Become your own weather expert.

ISBN 0 11 400312 2 244mm 240pp £4.95 (£5.49).

BookShelf

This is just a random selection of recent HMSO books. Hundreds more are issued every year. To keep abreast of them, ask for a FREE copy of our illustrated broadsheet *BookShelf*. Like spring, it is bursting out all over — with articles and reviews of new books on every subject under the sun. Thousands of readers receive *BookShelf* regularly under our free mailing list scheme. Why not you? Write to: HMSO, PM1C, Atlantic House, Holborn Viaduct, London EC1P 1BN.

All books are offered subject to availability. Prices in brackets include inland postage.

Titles available from Government Bookshops in London, Edinburgh, Belfast, Cardiff, Manchester, Birmingham and Bristol; from official agents for HMSO Books (See Yellow Pages); or through any good bookseller.

DAVID C. LINDBERG, editor Science in the Middle Ages

Major aspects of the medieval scientific enterprise are examined in depth in this illustrated volume; the contributors address themselves to topics central to their research and provide as full an account of medieval science as current knowledge permits. The book is not encyclopaedic: rather it interprets major developments in each of the disciplines that made up the medieval scientific world. *History of Science & Medicine Series* April 1979, 544 pages, 42 photographs and drawings, £28.00.

STILLMAN DRAKE Galileo at Work: His Scientific Biography

In this fascinating and authoritative biography the author argues (on the basis of the most thorough year-to-year review ever made of Galileo's life and work) that Galileo was, in the fullest sense, a man of science. By restricting his scientific claims to a narrow domain within which no appeal was made beyond sense, experience and necessary demonstration, Galileo hoped to avoid conflict with theologians and philosophical scholars. January 1979, 560 pages, £17.50.

JOSEPH J. SCHWAB Science, Curriculum and Liberal Education

Selected Essays

edited by Ian Westbury and Neil J. Wilkof

Schwab participated in what has been described as the "most thorough-going experiment in general education in any college in the United States", the College of the University of Chicago during the '30s, '40s and '50s. He played a central role in the curriculum reform movement of the '60s, and his extraordinary command of science, the philosophy of science, and traditional and modern views of liberal education found expression in these exceptionally thoughtful essays. January 1979, 408 pages, £16.80.

Ocean Yearbook 1

Elisabeth Mann Borgese & Norton Ginsburg, editors

April 1979, 800 pages, £17.50.

ROBERT GEROCH General Relativity from A to B

"Quite the most elaborate discussion of the fundamental aspects of relativity that I have encountered in a non-specialist book." *P. C. W. Davies, Nature*

November 1978, 240 pages, £8.40

W. E. LEGROS CLARK The Fossil Evidence for Human Evolution

An Introduction to the Study of Paleoanthropology
Third edition, revised and enlarged by B. G. Campbell
March 1979, 231 pages, £3.20 paperback.

New books from CAMBRIDGE

The Beagle Record

Edited by RICHARD DARWIN KEYNES

This is an account of the voyage of H.M.S. Beagle round the world told in the words of Darwin and Captain FitzRoy and illustrated with an exceptionally fine selection of water colours and pencil drawings made by Conrad Martens, the official artist of the Beagle.

'The Beagle Record is not only a magnificent book in appearance, its skilled and sensitive presentation of Darwin's and Captain FitzRoy's words (a significant amount of which are previously unpublished) also keenly evoke the sense of adventure, excitement, frustration and misery that both men experienced in their separate ways on the long voyage ... The Beagle Record is a great work about a great man on a great adventure.'

Gay-Lussac

Scientist and Bourgeois

MAURICE P. CROSLAND

Gay-Lussac lived through three revolutions in France and these had a profound effect on his life and career. He became one of the first professional scientists with full training and support. In his book, Professor Crosland gives an interesting and instructive account of the effect of this professionalism on Gay-Lussac's approach to science and of his rivalry with the British chemist Humphry Davy. Gay-Lussac was not only a leading figure in the French scientific establishment, but he also played a role in industry, commerce and in national politics.

'Professor Crosland has written a book with unusual features ... The book should be in all libraries, and will be rewarding reading to those who give it sustained attention and reflection.'

An Analysis of Primary Medical Care

An International Study

W. J. STEPHEN

This volume examines the provision of primary medical care or general practice in twenty-three different, predominantly developed countries, selected because of their variety and importance. The underlying thesis of this account is that the health of any population depends more on the availability of good primary health care than on the advanced technology and sophistication of modern hospitals. Dr Stephen justifies the continuing existence and expansion of primary care with the proviso that doctors must be prepared to make available an accessible and acceptable form of care for their patients. This stimulating and engaging account of very important issues for the health of all the peoples of the world will be of interest to anyone concerned with the provision of health services.

Reliable Knowledge

J. M. ZIMAN

In his book, Professor Ziman explores the grounds for belief in science, and in doing so he soon escapes the conventional bounds of the philosophy of science to search for relevant evidence for his argument that scientific knowledge is no more than an elaborate extension of every-day reality. Well-known episodes in the natural sciences have shown that accepted scientific knowledge must always be treated with scepticism. In view of the importance of scientific ideas in modern culture and the controversial growth of sophisticated technology this work should be of interest to every educated person.

'Prof. Ziman has produced a controversial and interesting "exploration" ...'

Man and Nature in the Renaissance

A. G. DEBUS

This book provides an integrated introduction to science and medicine from the mid-fifteenth to the mid-seventeenth century. It describes the key developments that prepared the way for modern science in the late seventeenth century. The book is illustrated with many beautiful contemporary pictures and is suitable for undergraduates and general readers with an interest in this area.

'... Allen Debus has produced an admirably balanced account of how Hermeticism, and Neoplatonic mysticism generally, affected the Scientific Revolution ... in its quiet way, this book represents a minor revolution ... It is skilfully done, and undoubtedly right in its general outlines.'

Encounter

'Professor Debus writes clearly and with an attractive brevity for the non-specialist reader.'

CAMBRIDGE UNIVERSITY PRESS

logical difficulties of validating science, "there is nearly universal human consensus concerning certain aspects of of the material domain". He leaves open the question "whether the categorial framework of everyday realism is the only possible scheme for describing and understanding nature in its physical aspects". He is content to leave it like this, but is not optimistic that "psychology and neurophysiology can arrive at a better understanding than, say, the ancient art of introspection"

Here I should disagree with him. Although he has taken the trouble to study these biological subjects seriously, I do not think he appreciates the speed with which they are approaching the capacity to achieve consensual communication that is useful even if not completely unambiguous. It is not too wild a statement to say that we are within sight of a 'complete' science of biology with principles that cover the origin, evolution and present operations of living things. It is true that the extension of this to include Man raises special difficulties. He rightly dwells in

his concluding chapters on the difficulties of precise definition of such concepts as "intelligence", "caste", "peasant" or "psychosis". In fact "we do not have a taxonomic framework for human behaviour, individual or social, in which the categories are both meaningful and distinct". True enough, and we all deplore the weakness of sociology. The difficulties introduced by hidden variables will of course always make the study of complex systems more difficult than that of simple ones. If the aim was to find some logically perfect science of man then indeed I should be pessimistic. But Ziman has taken pains to show us that the whole of science is simply an empirical, useful, predictive enterprise, characteristic of modern *Homo sapiens*. The life sciences are a part of this enterprise that is at present developing very rapidly, and I believe that his careful attention to them has already been very helpful and will be even more so in the future. □

J. Z. Young is Emeritus Professor of Anatomy at University College, London, UK.

Systematic theory of meaning

George Steiner

Truth and Other Enigmas By M. Dummett. Pp. 470. (Duckworth: London, 1978.) £18.

For Michael Dummett, Frege's *Grundgesetze der Arithmetik* is not only "unquestionably the most brilliant sustained performance of its length in the entire history of philosophy," but the whole of logic "came of age only with the work of Frege." It follows that the "most urgent task that philosophers are now called upon to carry out is to devise what I have called a 'systematic theory of meaning'." This systematic theory will proceed from the cardinal distinction between 'sense' and 'reference' in Frege and from Frege's concepts of the relationships between logic and mathematics on the one hand and logic and language on the other. Concomitantly, the philosopher, though fully aware of the attractive 'nihilism' in Wittgenstein's belief that philosophy is not "in the least concerned with establishing true propositions", will turn to Frege's systematic programme to establish a logical foundation for the determination of such propositions. And though, again, aware of the teasing finesse of Quine's thesis on the

indeterminacy of natural language propositions, he will reject this thesis. Only in this way, argues Professor Dummett, can philosophy aspire to a 'scientific' status and emerge from a 'scandalous' historical situation in which interminable effort and ingenuity "appears to engender nothing but unending disagreements."

Dummett's own papers represent this programme. They are closely-argued, rigorous and subtle steps towards a 'theory of meaning' capable of generating and testing a better understanding of 'truth', of the conditions under which a sentence may be correctly asserted, about whether the reality that renders key classes of empirical statements true or false can be shown to be fully determinate. These concerns are closely linked to a series of highly technical considerations (of special interest to the mathematician, to the mathematical logician but also, at several points, to the scientist in general) on the conflict between realists and intuitionists in mathematics, on the philosophical reach of Gödel's theorem and on the justification of deduction. Physicists, familiar with notions of time-reversal, will find much to instruct and delight them in two essays on "Can an Effect Precede Its Cause?" and "Bringing About the Past". Professor Dummett is a master of logic and of analytical exposition, and where one fails to agree—has he allowed for the characteristic and shrewd pragmatism which underlies Quine's thesis on the indeterminacy of translations between languages, a thesis which cannot be

Biology of Seaweeds

Levels of Organization

A. R. O. Chapman

By dealing in turn with cells, whole organisms, populations, and communities, this skilfully designed, clearly written text fills the need felt by many phycology instructors for an organizational approach for their courses on algal biology in place of the traditional texts that attempt to review the entire field systematically or by functional organization. The book focuses mainly on seaweed algae and emphasizes ecological considerations to point out the unifying trends and concepts that are essential for a student's thorough understanding of the subject.

Biology of Seaweeds is a stimulating and precisely targeted textbook for intermediate and advanced students of phycology. It reflects throughout Dr. Chapman's extensive experience as a teacher and his expert knowledge of algal biology.

Adaptation to Thermal Environment:

Man and his Productive Animals

Lawrence E. Mount

Contemporary Biology Series

This book deals with the principles underlying the heat exchanges that take place between an animal and its thermal environment, and with the application of these principles to man and to those animals that are of agricultural importance. The text is in two parts: the first part consists of six chapters dealing with the basic considerations that apply to the relations between an animal and its thermal environment.

The second part contains accounts of the different species.

Boards £16 Paper £7.50 Publication May

Soon to be available as a Student Paperback:

Plant Virology: The Principles

Adrian Gibbs and Bryan Harrison

This modern exposition of plant virology aims to describe the framework of knowledge about plant viruses and to outline the methods used in obtaining this knowledge. The numerous illustrations include superb electron micrographs—many of them original—and other photographs as well as numerous line diagrams. Thus the framework of the subject is provided and much practical information on how plant viruses can be studied is given.

simply reduced to an intralinguistic model?—one does so at one's peril.

Professor Dummett's conviction that "we have now reached a situation" where what he postulates to be *the* fundamental philosophic problem, the theory of meaning, "can be resolved to the satisfaction of everyone" and, above all, be successfully resolved "within a finite time", is one of radical innocence. It may have at its core a certain personal element—even the most abstract, analytical thought has a living presence and agent behind it. There are tantalising hints that even in respect of mathematics, Dummett's provisional realism has a theistic basis or that 'metaphysics' is for him far from being nonsense if a systematic theory of meaning underlies it. Indeed, says, Dummett, "If I have made any worthwhile contribution to philosophy, I think it must lie in having raised this issue in these terms." The implications are very wide and of the greatest importance.

It is the more regrettable that the two papers in which Dummett deals with the history of 'linguistic philosophies' in this country, and with the

attacks (however technically inept) made on the narrowness, on the purely technical scholasticism of these philosophies, should decline to engage the real issue. This issue is not whether Strawson has been misinterpreted or whether Ayer has seen the importance of Frege's logic. It is whether or not the concerns which Professor Dummett so brilliantly pursues are central, are adequate to the concept of philosophy in society and the lives of individuals. The charge, and Dummett does not answer it, is simply this: Oxbridge linguistic logic has trivialised the enterprise of the philosopher. It has sought to eliminate ethics, aesthetics, metaphysics in the very sense in which Dummett invokes it. It has chosen to ignore, in Owen Chadwick's remarkable phrase, the extent to which, since the 1930s, "the agonies and passions of mankind started to enter and complicate the philosophies." The challenge is a real one. No-one would meet it better than Professor Dummett himself. □

Panorama of modern neurobiology

Leslie Iversen

Molecular Neurobiology of the Mammalian Brain. By P. L. McGeer. Sur John C. Eccles and E. G. McGeer. Pp. 644. (Plenum: New York and London, 1978)

THIS substantial volume represents the results of an ambitious undertaking by two biochemists who have pioneered the application of biochemical approaches to studies of chemical neurotransmitters in the brain, and one of the most eminent neurophysiologists of our time. An ambitious undertaking because they seek to bring together in one volume virtually all of the achievements of modern cellular neurobiology and to show how far this basic information can be used to explain the integrative functions of the mammalian brain. This is promising stuff, and the reader is further encouraged by the authors' principle that they should provide not merely a bare factual account of present knowledge, but attempt to give some outline of the key events in the historical development of such knowledge from the interplay of hypothesis and experiment. We may even hope that the basic cellular data will

throw some light on the workings of the human brain—"This organ, weighing about 1.5 kg, is the most highly organised matter known in the universe".

The *Molecular* title indicates a leaning to the 'wet' approach to neuroscience, which emphasises the explanation of brain function in chemical terms; but this is in fact misleading, as virtually all aspects of cellular neuroscience are dealt with in the first and largest two sections of the book. These, in some 360 pages, review basic information on the architecture, organisation and signalling properties of neurones, and concepts of chemical synaptic transmission in the periphery

and in the central nervous system (CNS). A series of fairly detailed chapters summarise current knowledge of the specialised biochemical properties associated with neurones using acetylcholine, amino acids, catecholamines, or 5-hydroxytryptamine as transmitter, and others cover the new field of 'promising peptides' and various other putative CNS transmitters, accompanied in each case by a brief outline of the actions of drugs on neurotransmitter mechanisms.

The coverage of neurotransmitters is good and up to date, although more explanation and examples could have been given of ligand-binding techniques for the study of neurotransmitter receptors in CNS, a development which has had a major impact on neurochemical studies of such mechanisms in recent years. The undue emphasis given to acetylcholine and catecholamines (almost 100 pages) continues to reflect the inadequacy of our current knowledge of other CNS transmitters, rather than the true importance of the monoamines in CNS function.

A third section of some 200 pages gives a wide-ranging review of integrative aspects of brain function, from development and plasticity to motor control mechanisms, learning and memory, and perception, speech and consciousness. The aim is to refer back in this section to the basic properties of neurones described previously. This aim is sometimes successfully achieved: for example, in the description of the extrapyramidal motor control systems in basal ganglia, in which anatomical, physiological and neurotransmitter aspects are well integrated, with discussion of human basal ganglia disease, such as Parkinsonism and Huntington's Chorea and their treatment by drugs, neatly interspersed. On the other hand, the description of cerebellar function completely omits any mention of the neurotransmitters involved, despite reference in earlier sections to the important role of the putative amino acid transmitters, γ -aminobutyric acid and glutamate, in this region of the brain. An ambitious chapter on basic aspects of behaviour includes a description of central endocrine influences and the CNS actions of psychoactive drugs, together with a review of current neuropharmacological theories of mental illness. As complexity increases with each succeeding chapter it is inevitable that the book ends with a discussion of perception and consciousness, in which the dualist-interactionist hypothesis—described in more detail in the recent book by K. R. Popper and J. C. Eccles *The Self and Its Brain* (Springer: Berlin, 1977; for review, see *Nature*, 272, 770, 1978)—is restated. The reader is given plenty of advance warning of this conclusion: in discussing the ques-

NEW GEO-SCIENCE TITLES FROM ELSEVIER...

Man's Impact on Climate

edited by WILFRID BACH, JÜRGEN PANKRATH and WILLIAM KELLOGG

(Developments in Atmospheric Science, 10)

This book contains the Proceedings of an International Conference held in Berlin in June 1978. It provides an up-to-date review of our present knowledge of climatic change by studying climate history, theory and modelling; man-induced external causes of climate change; and the potential climate changes for different energy scenarios.

ISBN 0-444-41766-4

Remote Sensing of the Atmosphere

Inversion Methods and Applications

edited by ALAIN L. FYMAT and VLADIMIR E. ZUEV

(Developments in Atmospheric Science, 9)

This volume contains a selection of refereed articles, by leading international experts, presented at a Symposium held during the Second Special Assembly of IAMAP in Seattle, Washington, 1977. It covers the three main areas of remote sensing of the atmosphere (temperature, gaseous and particulate composition) and the boundary surface, from methodology to ground-based and space experimentation using passive and active means (infrared and microwave radiometry, visible imagery, laser radar).

Elastic Analysis of Soil-Foundation Interaction

by A. P. S. SELVADURAI

(Developments in Geotechnical Engineering, 17)

This is the first book to give a unified treatment of the elasticity aspects of soil-foundation interactions, an extensive state of the art study, and an up-to-date list of all major articles published on the subject during the last 50 years.

Supplemented throughout with clear illustrations, the book brings together all the theoretical and experimental advances in this field, providing geotechnical, civil and mechanical engineers with a valuable source of reference.

Stability of Tidal Inlets Theory and Engineering

by PER BRUUN

(Developments in Geotechnical Engineering, 23)

From empirical and often unreliable rules and formulae, the engineering science and technology of the stability of tidal inlets of littoral drift shores has recently developed into an exact science based on the results of physics and hydraulics. This book covers, in detail, the theoretical and applied aspects of the science from basic coastal geomorphology, hydraulics, wave mechanics and sediment transport technology, to engineering of tidal entrances, design and improvement of inlet channels and their maintenance.

INCLUDING A NEW JOURNAL

Geo-Processing

Geo-Data, Geo-Systems and Digital Mapping

Editor-in-Chief: T. K. PEUCKER, *Simon Fraser University, Canada*

For all those interested in the different types of spatial information systems, this new journal brings together developments in such specialised systems as geo-coding, thematic and topographic mapping, land use and resources, cadastral, and digital terrain models. It covers the collection of data where geographical coordinates are involved and their editing; conceptual structures and data structures of regional information systems; methodo-

logy for the analysis of spatial data and the techniques for their display. The two main types of article appearing in the journal are: scholastic papers of high standard, presenting original research and development; and surveys providing summary accounts of the developments taking place in the various sub-fields.

1. **ICE AGES: Solving the Mystery**

John Imbrie & Katherine Palmer Imbrie

This book presents the recent findings on ice ages and puts them into perspective. It describes some of the colourful people who have been engaged for nearly a century and a half in the search for a solution to the ice age mystery. In short, it tells the story of ice ages: what they were like, why they occurred, and when the next one is due.

£6.95 224pp 264 × 160mm illustrated
0 333 26767 2

2. **GENERAL RELATIVITY AND COSMOLOGY**

Professor J.V. Narlikar

The author analyses critically General Relativity as applied to cosmology and presents a thorough survey of current cosmological theories. Among the hypotheses which Narlikar examines in great depth is that which proposes two gravitational constants, viz. the Hadron constant, and the Einstein constant.

£9.95 304pp 0 333 24153 3

3. **GENETICS OF HUMAN POPULATIONS**

Albert Jacquard

This is a unique introduction to the population genetics of the human species. It explains the hypotheses needed to compare observations of human populations with the theoretical genetics models and demonstrates how this approach contributes to a better understanding of Man.

£12.00 192pp 234 × 156mm
0 333 25654 9

4. **PLANT BREEDING AND GENETICS IN HORTICULTURE**

C. North

Science in Horticulture Series

Starting from basic principles, the book describes the cytological mechanism of inheritance and the segregation of plant characters. Background information is given to enable the reader with no prior knowledge of genetics to understand the basis for plant breeding techniques. Practical breeding techniques are then described in some detail using, almost exclusively, examples of horticultural plants.

11. GUIDE TO LIVING REPTILES

Professor J.E. Webb, Dr. J.A. Wallwork & Professor J.H. Elgood

Intended for undergraduates taking courses in vertebrate zoology and, in particular, in reptile biology and zoogeography, this presents a comprehensive yet detailed view of the diversity of reptile life coupled with an up-to-date scheme of classification which brings order to this diversity.

£3.95 172pp 216 x 138mm 0 333 25653 0

12. STRUCTURE AND FUNCTION OF THE CEREBRAL COMMISSURES

I. Steele Russell, M.W. van Hof and G. Berlucchi

This book marks a turning point in the rapidly growing field of commissure research. The 39 papers presented here reflect the broadening of investigations – from concentration on Primates to research into the commissures of simple mammals, lower vertebrates and birds. This comprehensive work will be of considerable value to all workers in the neurosciences, and to psychologists, primatologists and zoologists.

£20.00 520pp 234 x 156mm 0 333 23410 3

13. INBRED STRAINS IN BIOMEDICAL RESEARCH

Michael F.W. Festing

This, the first book to be written about inbred strains in laboratory vertebrates, covers the origin, maintenance, nomenclature and properties of inbred strains, and explains how such strains have been used in research, sometimes as disease models and sometimes as tools.

£25.00 496pp 234 x 156mm 0 333 23809 5

14. DISCRETE EVENT MODELLING ON SIMULA

G.M. Birtwistle

Computer Science series

This is a primer on discrete event modelling in DEMOS, an extension to the general purpose language SIMULA. DEMOS programs have been adapted to conform to a very simple format which can be written and understood without a specialist knowledge of SIMULA, and should thus be of great interest to undergraduate and postgraduate students alike.

NEW WORKS ON EARTH SCIENCES

CATALOGUE OF CHEMICALLY ANALYSED IGNEOUS ROCKS in the British Museum (Natural History) by D. T. Moore, V. Jones, A. R. Woolley and A. C. Bishop. 1979 Paper covers, 4to.

From a scientific rather than an historical viewpoint, the most valuable material in the rock collection of the British Museum (Natural History) is undoubtedly that which has been chemically analysed. Although many of the analysed rocks in the collection were described by the Museum staff, much of the material was presented to the Museum and its presence in the collection will not be widely known. This catalogue of analysed rocks held in the Museum, and from which samples can be made available, should prove of value to research workers. The analysed rocks are arranged in decreasing order of silica content, the index of rock names enables any particular rock type to be found quickly.

tion of consciousness (p3) "We shall see that it is beyond our comprehension how these subtle properties of the conscious self came to be associated with a material structure, the human brain, that owes its origin to the biological process of evolution." However, whether one agrees or not with this strong dualist stance, we could all agree that "We believe it to be important for the molecular neurobiologist to be confronted with the problems arising in higher brain functions."

In any volume with as wide a scope as this one, each of us will no doubt find what seem to be important omissions or failures of emphasis. For example, I found it hard to understand why so little attention was given to a clear description of modern anatomical tracing techniques, using anterograde and retrograde flow of marker materials, in view of the enormous and continuing impact such techniques are having on our understanding of neuronal circuits in mammalian CNS. (Pick up any current issue of a brain research journal and count the number of papers involving peroxidase tracing methods!)

The overall impression left by this book is that of a courageous enterprise which did not quite succeed in its objectives. The variation in styles between the authors is often very obvious, and this together with the attempt to cover almost *all* aspects of mammalian neurobiology inevitably makes the book somewhat disjointed, with the individual chapters often divided and sub-divided over again into a multitude of smaller subsections. The illustrations, however, are copious and of excellent quality, and there is a substantial bibliography, with more than 1000 references (though with few more recent than 1976). One is left with admiration for the energies of the authors who have succeeded in putting together an attractive volume, but also in some doubt as to its likely readership. The book is probably too large and expensive to become widely used as a neurobiology student text, where other excellent volumes in any case already exist—for example, S. W. Kuffler and J. G. Nicholls' *From Neuron to Brain* (Sinauer Associates: Sunderland, Massachusetts; UK Publisher, Place, 1976). Nevertheless, it deserves to find a wide readership, and will certainly provide an accurate and sometimes inspiring panorama of modern neurobiology for those who want to know more about the field as a whole, or who feel the need to bring up to date what they thought they once knew. □

Boundaries of palaeo-anthropology

G. E. Kennedy

Early Hominids of Africa. Edited by C. Jolly. Pp. 598. (Duckworth: London, 1978.) £28.

HISTORICALLY ill-defined, the boundaries of palaeoanthropology have recently been delineated by several excellent volumes. Although all of these volumes have emphasised the interdisciplinary character of palaeoanthropology, none has so effectively designated the scope and nature of the contributions from geology, anatomy, biology and archaeology better than this one.

Early Hominids of Africa is comprised of papers given at a conference held in New York more than five years ago. That the conference was organised (largely by Cliff Jolly, who also edited the volume) with care and some foresight is attested to by the overall currency and freshness of the papers. A number of the papers are, in fact, of considerable value in designating the current structure of the discipline.

Glynn Isaac, in his contribution, for example, discusses the scope of palaeolithic archaeology within the context of palaeoanthropological investigations. He points out that such studies focus less on traditional questions of tool typology and more on broader areas of tool function and the behaviour, selection and origin of raw materials. His suggestion that tools represent "self-recording behaviours" typifies the approach where more detailed and subtle questions are now asked of empirical data than was usual in earlier years.

So, too, with the palaeoecological papers contributed by Butzer, Behrensmeyer and Cooke. These papers, each from a different research perspective, focus on the reconstruction of the environmental context of the early hominids. Butzer's paper is perhaps the most successful of these and indicates the new directions taken by the various contributory disciplines within the context of palaeoecological reconstructions. Butzer argues that many of the environmentally deterministic models of anthropoid and hominid evolution were erroneously based on unidimensional reconstructions and both the

environment and the sources of selective pressures were more complex than the earlier, more simplistic models would allow.

The section on anatomical evidence, the largest in the book, reflects a strong trend in research interests away from the cranium; all but two of the papers deal with analyses of postcranial anatomy and locomotor capabilities. Papers by Day, Robinson and Lovejoy are informative in these areas, although they provide little that has not been published elsewhere. The two papers on cranial morphology are innovative and highly specialised. Wallace's study on the ramifications of early closure of the premaxillary suture in hominids is both insightful and soundly based on the fossil evidence. His discussion on the ontogenetic, phylogenetic and adaptive aspects of this process is an excellent example of the subtlety of the questions now being asked of the fossil data. So, too, with Holloway's discussion of endocranial casts which continues his series of stimulating, frank and challenging papers.

A section devoted to the interpretation of diversity in early hominid samples continues the interdisciplinary theme. Delson's paper on cladistic analysis, which emphasises trait congruity as a taxonomic tool, contrasts strongly with Campbell's, which seems to emphasise temporal congruity for the same purposes. Simons contributed an analysis of hominid evolution from a vertebrate palaeontologist's viewpoint. Although valuable for methodological as well as interpretative reasons, this paper is of particular interest for its discussion of *Ramapithecus freybergi*, a later Miocene hominid from a site near Athens.

Papers on the most productive of the east and south African localities were submitted by the sites' principal investigators. Although much of this information has been published elsewhere, these concise summaries are useful.

The long delay in publication has resulted in very few shifts in the interpretation of data. The most noticeable of these shifts involves Johanson's evaluation of hominid material recovered at Hadar, Ethiopia. In 1972, he suggested that two taxa were present at Hadar, a view recently formally rejected in favour of a single taxon. The only significant criticism which can be levelled at this volume is the cost. The high price will put it beyond the reach of most advanced undergraduate and graduate students, groups which would benefit most from it. □

Technological medicine

Maurice Lessof

Beyond the Magic Bullet. By B. Dixon. Pp. 249. (George Allen and Unwin; London, 1978.) £5.50.

THE essential thesis of this readable and well written book is that expensive, technological medicine has failed. It has distorted our approach to health problems and has led to the neglect of the epidemiological, social and psychological components of illness. Worse than this, it is not even effective. Waterborne infections, which kill an estimated 10 million people annually throughout the world, could be contained more readily by measures that are concerned with nutrition, hygiene and water supplies than ever they could by antibiotics.

There is a second theme which is a little more difficult to sustain. The author believes that, in a world setting, the approach to disease through individual causes and specific cures has largely been a fiasco. 'Specific aetiology' is an idea that has had its day; for even infections with an identified cause are very complex in their origins. A technological approach to treatment is inappropriate in the Third World, where the death rate for measles is increased 400-fold by malnutrition.

The fallacy of this proposition is perhaps worth considering, for the argument is very seductive. The use of vaccines, much applauded by the author, is the fruit, *par excellence*, of research into 'specific aetiology'. It is also, incidentally, a product of the much-criticised pharmaceutical companies, with their 'magic bullet' mentality. In making the case for better nutrition and hygiene, it is tempting to deride the scientific approach. Yet vaccination has eradicated entire diseases from many countries throughout the world. The evidence of this book, so impressive in other ways, cannot therefore be accepted for this curiously science-bashing purpose.

The author's thesis is a powerful one and may be re-stated in another way. The Western approach to medicine is characterised by a search for antidotes and glamorous technology. It has led to overspecialisation, overprescribing, and the development of incongruously elaborate techniques for curative medicine and surgery. It fails to take into account the fact that the illnesses of mankind are determined by a combination of many factors, which require social remedies rather than pill-pre-

scribing and high-technology doctoring. In the West, cigarette-smoking and obesity, in the Third World nutrition and hygiene—these should receive our attention and our emphasis.

In its writing, this book is delightful, and the historical section includes an account of Pasteur's experiments which is strangely exciting. (Poor Jenner gets no credit, but never mind!) The author is not merely an anti-medical Illich, following a fashionable witch-hunt against doctors. He notes that some at least of the medical profession share his concern with the relationship between social problems and health care. The medical establishment is, however, unable to cope.

The problems are indeed formidable—how to assert, in a liberal democracy, an effective anti-smoking, anti-alcohol, anti-obesity policy; how to persuade a Third World country to modify, however slightly, the priority given to prestige hospitals and universities, in order to emphasise the importance of hygiene, health education and good water supplies; and how to encourage solutions which, even when they cost nothing, require a firm stand by politicians, who themselves depend on populist support.

Much of the quoted evidence is beyond dispute. There are some massively important problems, which we neglect at our peril and which require largely political solutions. The medical or scientific reader may find little comfort in the author's message. The implication, almost throughout, is that the purveyors of modern, conventional medicine and research are oblivious to the real world, shackled to an obsolete view of current health needs, obsessed by high technology and magic bullets, and unable or unwilling to adapt either their thinking or their teaching of the next generation of doctors. This is simply not true. The problems are as formidable as the author says they are. In seeking to combat them, it needs to be more clearly stated that doctors, and even scientists, are quite frequently on the side of the angels.

Switching from the Third World to the sophisticated West, there is not only a need to change our social priorities but also a need for more humanity in our provision of health care. This is illustrated by a vivid account of a patient with ankylosing spondylitis, who had an unquenchable determination to get better, though "one of the experts put the chances of recovery as one in 500; another said he had never witnessed recovery from this comprehensive state". (On the story given, this was probably not ankylosing spondylitis at all but post-infective reactive arthritis, from which a rapid recovery is usual. Even in true anky-

losing spondylitis, it should be stated that some 80–90% of patients are earning their own living 20 years later.) The story is a good one, recording a patient's determination and also a doctor's unstinting support for an unconventional treatment which had nothing to commend it except for the patient's faith. The point is well made. A practising doctor looks after sick people, not disembodied disease. Hope and encouragement may do more than medicine—even more so in diseases such as cancer, in which definitive medical treatment may not be available.

Having reviewed all the evidence, this book suggests that we must deploy both our doctors and our financial resources to better effect. The message could, however, be dangerously misread. On the advice of our politicians, we in Britain have already suffered an expensive and ineffective reorganisation of the Health Service; a wasteful but well-meaning allocation of money to ineffective types of social work; a crazy emphasis in our Community Health Councils, which give priorities to 'watchdog' functions rather than to a responsible collaboration with professional health workers; and an opportunistic encouragement of specialised kidney units which are now, for political reasons, deprived of funds.

What about the needs of the Third World? Who can doubt that great benefits could follow from better nutrition, hygiene, good water supplies, and the Chinese barefoot doctor's approach to health education and simple health care. But even here, the problem is not a simple one. In many parts of the world the mere fact of a reduced infant mortality rate results in the exposure of even more children to the ravages of malnutrition. In this context, social priorities must therefore include population control. This, the most important problem of our time, is merely touched upon in this book. Alone among the Third World countries, the Chinese have shown that population expansion can be controlled by means of public education and persuasion. In the West, however, this social and political approach has not succeeded. Here the contraceptive pill and the intra-uterine device have, indeed, provided another victory for high technology, and their future potential blessings have yet to be realised.

In summary, the siren song of the anti-science lobby needs to be heard but then resisted. The moral to be drawn from this book is absolutely clear. We need both social policies and high technology to solve our problems. It is a partnership, not a conflict. □

Maurice Lessof is Professor of Medicine at Guy's Hospital, London, UK

Complex mental functions

Kevin Connolly

Mind in Society: The Development of Higher Psychological Processes. By L. S. Vygotsky. Edited by M. Cole, V. John-Steiner, S. Scribner and E. Souberman. Pp. 159. (Harvard University Press: Cambridge, Massachusetts, and London, 1978.) £8.75.

L. S. VYGOTSKY is known largely to the English reading community through a little book, *Thought and Language*, which has received very wide acclaim. It was published posthumously in 1934, suppressed in 1936, reissued in 1956 and translated into English only in 1962. The book has had a great impact on Western psychology and revealed Vygotsky as a truly original thinker and insightful observer of children. He was born in Orsha in Byelorussia in 1896 and graduated from the University of Moscow in 1917 having specialised in literature. From 1917 to 1923 he taught literature and psychology in a school and began his systematic work in psychology only in 1924. In 1934 at the age of 38 he died of tuberculosis. During this all too brief period of research in psychology he was immensely productive. He worked first at the Institute of Psychology in Moscow and then in the Institute of Defectology, of which he was a founder. Over this 10 year period he taught courses in Moscow and Leningrad, undertook a medical training, and wrote more than 160 books, papers, reviews and lectures. Much of this work remains unpublished and very little has been translated into English. It is now over 40 years since Vygotsky died and yet much of what he had to say is fresh and deeply significant for contemporary psychology. This newly-translated material is of historical interest but not primarily so; he was writing clearly about fundamental issues which Western psychology has recently been congratulating itself on having articulated.

Vygotsky was interested in complex mental functions, or as they were more usually called 'higher psychological processes'. He rejected the notion that an understanding of these processes could be gained from an extension of the principles derived from animal psychology, and like the Gestalt psychologists did not believe that an adequate analysis was to be found in

reductive stimulus-response theories. He sought a comprehensive approach which would provide both description and explanation in terms acceptable to natural science. His goals for such a programme were immensely ambitious including as they did the identification of relevant brain mechanisms, the developmental history of behaviour, and most important specifying the societal context in which the behaviour developed. That he did not fully achieve these goals is hardly surprising but he did show himself to be an astute and remarkable thinker.

For Vygotsky the developmental method is a central feature of psychological science. He saw the scientist's task as one of reconstructing the origin and course of the development of behaviour and consciousness. A distinctive theme of his writing is the emphasis which he placed upon the unique qualities of man. As a species we actively realise and change ourselves in the varied contexts of history and culture; in the course of his history man affects and changes nature to create for himself new conditions of existence. To the Western tradition Vygotsky seems less an experimenter and more a thinker. He was a brilliant observer of children and an ingenious experimenter, but his work is not characterised by elaborate experimental designs and statistical analyses. Rather the experiment is a means of gaining insights which illuminate the ideas and carry them along. The experimental 'leg work' will no doubt be done by others, who perhaps find thinking harder.

The book contains eight of Vygotsky's essays, the first five of which are taken largely from a hitherto unpublished manuscript of 1930 entitled, *Tool and Symbol in Child Development*. Here Vygotsky attempts to relate Marx's Theory of Society to concrete psychological questions. The concept of tool implies a specific human activity, the transforming effect man has upon nature in gaining mastery over it to serve his ends. Like tool systems, sign systems (speech, writing, number) are created by societies and change with the level of cultural development. In this way the mechanism of individual developmental change is rooted in society and culture. The last three essays explore educational implications of his ideas. Again the penetrating quality of his thought is striking. He explores the relationship between learning and development, and in his concept of the "zone of proximal development" can be seen the antecedents of the competence/performance distinction which psychologists have made much of over the

past decade. He proposes too that intelligence could be better assessed by an examination of the child's capacity to benefit from teaching rather than the normative comparisons embodied in psychometric tests. In an essay on play he concludes that it is not a predominant feature of childhood but that it is a leading factor in development. The last essay on writing is a masterpiece which has profound practical implications in education.

This little book is an intellectual excitement; it abounds with all manner of ideas, insights and novel formulations. For anyone feeling jaded with contemporary cognitive or developmental psychology the book should lift the spirit; for the graduate student in search of ideas it cannot fail to raise and widen the horizons. The editors provide, two by two, a useful and sharply focused introduction and concluding piece.

Vygotsky comes high on my list of people I regret not having met and I am grateful to the editors for having helped me know him in the next best way. I recommend the book warmly and without reservation. □

Invitations to enquiry

Mary Waring

Science, Curriculum, and Liberal Education: Selected Essays. By J. J. Schwab. Edited by I. Westbury and N. J. Wilkof. Pp. 394. (University of Chicago Press: Chicago and London, 1978.) \$24; £16 80.

For some twenty-five of his fifty years at the University of Chicago, Joseph Schwab participated in an experimental undergraduate programme in general education, and it was this experience that gave impulse and direction to all his writing. This book contains a selection of twelve of the fifty or so essays that make up the bulk of his published work, an Introduction written by the Editors, and a bibliography.

The Introduction outlines the context in which Schwab's ideas developed. It stresses the continual interplay between, on the one hand, reflection upon the immediate practical concerns of his day-to-day teaching and, on the other, extensive explorations in psychology, psychiatry, literature, philosophy, science and the philosophy of science, an interplay that was to become the hallmark of his approach to education. His mastery and use of many perspectives and this interrelating of ideas and action gave Schwab both an intellectual framework and an integral and distinctive approach to problems. Both were greatly enriched by continuing dialogue with colleagues like Louis Thurstone, Irving Lorge, Ralph Tyler, Robert M. Hutchins and, above all, Richard McKeon, who introduced Schwab to hermeneutically-inspired interpretative schemata and, as a former student and colleague of John Dewey, gave him direct access to a philosophy that was to be a major influence on his thought.

Although many of the essays are well known and highly regarded, the fact that most have been written for special occasions and purposes and have hitherto been published individually in a variety of journals, has meant that they have proved difficult for many readers who have come to them in isolation or at relatively long intervals of time. Collecting them into one volume and providing the orientation afforded by context creates a whole which is much more than just the sum of its parts; it reveals so vividly the comprehensiveness and coherence of Schwab's understanding and it encourages and facilitates greater fluidity

of thought on the part of the reader. Grouped under three headings ("On Liberal Education and Science", "On the Foundations of the Curriculum" and "On Curriculum Building"), the essays are concerned primarily with a carefully reasoned enquiry into the practical problems of giving new meaning and vitality to the conception of a liberal and liberalising education and, within it, to the teaching of science. Schwab leads the reader through the complex web of considerations which enmeshes each of the issues explored—enquiry and interpretation, personhood and experience, scientific enquiry and the nature of science and liberal education, educational testing, teacher education and curriculum development and research—providing a series of deep insights and provoking reflection upon the articulation of ideas and action in the search for means and ends. There is no attempt, however, to argue for

outdated, elitist conceptions of liberal education: the concern is with the search for essentially practical ways of helping the young to become 'actively intelligent' people who enjoy and thus continue to seek out knowledge and understanding, and who possess the critical and organising powers that make possible informed choice and action.

This is a challenging and important book, offering none of the slogans and easy solutions of those whom Schwab describes as "honing a problem down until it looks simple" or basing their ideas on "unexamined notions of reality". Emphasising, always, that matters of the curriculum are matters for doubt and critical enquiry, Schwab is concerned to "move men to action", rather than to prove or to prescribe.

Mary Waring is Lecturer in Education at the Centre for Science Education, Chelsea College, University of London, UK.

A forbidden transition

Fred Dainton

Higher Education Developments: The Technological Universities, 1956-1976. By P. Venables. Pp. 407. (Faber and Faber: London, 1978.) £25.

This book has a simple structure. In the introductory chapter the reader is taken at a brisk trot through the history of post-school technical education by way of the Percy Report; the establishment in 1956 of the Colleges of Advanced Technology (CATs), and of the National Council for Technological Awards; the Robbins Committee's recommendations of 1963, most of which were accepted almost immediately by the Government and which led to the CATs being transformed into technological universities with a consequential transition from ownership and government by Local Authorities (or Government in the case of Loughborough); to self-government and financial support from the University Grants Committee (UGC). The next eight chapters are a description of all that happened in and to these institutions in the decade 1966-1976. This section is abundantly provided with graphs and tables and is a gold-mine of factual information which is made very easy to quarry by the use of a very well constructed index. The tenth chapter is entitled "The Polytechnics" and is in fact a fascinating comparison of these institutions with the technological universities, in which the author seems to

invite—almost quizzically—the reader to look at the facts assembled in four tables and draw his own conclusions. In the last two chapters the author looks at higher education in a broader perspective, as it is and as it is likely to be, and he also lifts the veil ever so discreetly on his own credo and ideals. The book ends with four appendices; a glossary of acronyms, potted biographies of the eleven institutional actors; a few more statistics which I feel would have been better placed in the text; and the questionnaires which evoked the responses on which much of the information purveyed by the book is based. The wealth of data assembled in the book contrasts somewhat strangely with a curious omission. Nowhere did I find a really clear definition of technology and how it should be distinguished from natural science and engineering—if it is.

The non-British reader may be surprised that a whole book should be devoted to the detailed examination of such a small subject—namely, the emergence, infancy and early childhood of eleven institutions containing only about one-tenth of the total university population and therefore only about half that proportion of the total in higher education. The significance of the subject does, however, go far beyond what this mere numerical comparison might suggest, for the process by which the technological universities were created can never be repeated for as long as the policy of the "binary system" holds sway. That transformation would now be a "forbidden transition". The book is therefore important as a case study of special value to two groups of people. On the one hand it will be important to those who will determine future tertiary education policy in Britain and on the other hand to the historians

of the politics of education. It can be strongly recommended to both because it is soundly based on a careful scrutiny and scholarly evaluation of documents and an exhaustive enquiry; above all, it is written by an "insider" (the author's own term). This last point is of special importance for although there are many pieces, published and unpublished, which are written about higher education in Britain few of the authors have Sir Peter Venables' very wide experience. These writers fall into a very wide range. Thus at one extreme the authors are lonely scholars, either MA or PhD thesis writers or their own senior colleagues, more often than not embedded in a School of Education, itself on the fringe rather than in the mainstream of the activities of its parent institution. Such authors' sources are restricted to public documents and their experience is unlikely to embrace that of treading the corridors of a local education authority, the Department of Education and Science, the Scottish Education Department, the Welsh Office or even the UGC. The fruits of their labours are, however, likely to be published perhaps in book form or as articles in journals for all to see, dissect and evaluate. At the other extreme there are the civil servants whose duties are to prepare influential position (and policy) papers which rarely ever find their way into the open literature—at least legitimately. Their own direct experience of higher education is likely to have been limited to a few years at a university ten, twenty or even thirty years earlier. So the scholar suffers from ignorance of the "real", as distinct from the "openly acknowledged", political and intellectual reasons for decisions; and the civil servant who is well placed to influence those decisions has no living, working contact with the "coal-face" of higher education.

This gap is deplorable, as it is likely to militate against the formulation of the most beneficial policies. How is it to be bridged? The Royal Commission is one device. It is certainly open and thorough but also often cumbersome and slow; and it is not a permanent bridge. There are a few helpful signs in, for example, what seems to be a greater willingness and/or freedom of the public servant to discuss issues with scholars and researchers and the welcome tendency to issue "Discussion Documents" and "Green Papers" before decisions are taken. Then there is the occasional forum or symposium which is, however, rarely productive of meaningful interaction between the civil servant who, restrained by the rules and conventions of his employment, may elect to stay silent at a public gathering on just those topics which, being of greatest contemporary interest and importance, are therefore also the most sensitive issue.

The situation would be much improved if there were some exchange of people between posts in Academe and the Public Service. But mobility, though repeatedly

advocated as desirable, remains and is likely to remain far too infrequent. In our British system the best we can hope for is the lucky chance either that academics and ex-civil servants are able to collaborate (as in the case of Becher, Embling and Kogan's brief study of higher education) or that some able person who has been deeply involved as a teacher and administrator in higher education institutions for most of his life, helping to shape them during a period of rapid development, who has also served on many national bodies in ways which have brought him into close contact with civil servants, local authority officials and politicians, will make time to take stock of the past and present and point out the options for the future.

Such a man is Sir Peter Venables. His career in higher education, especially in technological universities and their precursors, will be known to many as

qualifying him well for this task, to which he has also brought the scientist's insatiable appetite for facts and a method of enquiry borrowed from the woman who is both his sociology instructor and wife. The result is predictable and well worth the effort. I have only two regrets. The style is almost too 'dead pan', too detached and at a number of places I would have liked Sir Peter to be a little more 'unbuttoned' and to have given us the benefit of his own opinions even when they could not be completely buttressed by evidence. His own long and devoted service to the cause of technological education have earned him that right. My second regret is that the price should be so exorbitant and therefore the book may not get the circulation it deserves. □

Sir Frederick Dainton was, until 30 September 1978, Chairman of the University Grants Committee, London, UK.

Energy melting pot

Peter Rost

Energy and the Environment: Democratic Decision-Making. Edited by C. Lenzer, C. Phipps, J. Valleix and J. Surrey. Pp. 141. (Macmillan: London, 1978) £5.95.

It was not until the oil crisis of 1973-74 that politicians woke up to realise that they now had to face yet another challenge. Until then the provision of energy at an acceptable price was taken for granted. Energy policy was regarded as the preserve of technical experts and the balance between supply and demand was satisfied by the market. Now energy has become a dominant world political problem.

The energy debate has not lacked documentation. Students anxious to be alarmed, or reassured about the prospects for mankind's future energy resources have been deluged with reading material. But each such contribution to the argument has been a personal interpretation, or a consensus by an expert group. What has been less readily presented to the informed but enquiring reader, is an actual cross-section of the debate itself.

This is why this book is an important contribution to the evolving energy debate. It records a two-day colloquy organised in November 1977 by the Council of Europe, which brought together 70 politicians from Europe and North America, with an equal number of independent experts. The Parliamentarians represented a formid-

able array of spokesmen many of whom have established their national and international political reputations for their specialist contributions to energy studies, whereas the technical and industrial experts included many reputable figures from international organisations concerned with energy problems, of high standing in scientific, academic and international circles.

Such a rich mixture into a two-day melting pot could easily have created an indigestible meal. But the themes were well defined and the debate was disciplined. Four principle aspects were tackled—energy supply and demand to the year 2000; the contribution of fossil fuels and renewable sources; the nuclear debate; and options for the future.

Perhaps surprisingly, some consensus emerged. No one energy source will solve the future, real costs will rise and conservation must move up the league table of priority options.

Revealing too, is the admission by decision takers, that they (the decision takers) will have to face up to unpopular measures! Long term policies to provide enough energy, yet protect the environment, maintain living standards and preserve democracy, may require electorally unpopular choices.

This book should help to reassure the informed public that, although the experts will never agree any more than politicians, at least the debate is being carried forward on solid intelligent foundations of scientific knowledge and political maturity. We must hope that Parliamentarians will follow up with the correct policy decisions. □

Peter Rost is Member of Parliament for South-East Derbyshire, a Member of the Select Committee on Science and Technology Sub-Committee on Energy Resources, and Member of the Conservative Parliamentary Energy Group.

Civil nuclear policy

Walt Patterson

The Politics of Nuclear Power. By Dave Elliott, with Pat Coyne, Mike George and Roy Lewis. (Pluto Press: London, 1979.) Paperback £1.95.

THERE cannot be many issues which would bring John Biffen, MP, and Robin Cook, MP, into the same voting lobby at the House of Commons. Each is generally considered to be well toward the outer flank of his party—Biffen toward the right of the Conservatives and Cook toward the left of Labour. Yet on 15 May 1978 Biffen and Cook were together among the 80 Members who challenged the joint wisdom of both Front Benches and voted against the proposed expansion of nuclear fuel reprocessing at Windscale. Articulate Parliamentary critics of British civil nuclear policy, whose numbers have increased impressively in the past two years, speak from virtually every corner of the House—as do nuclear advocates.

It is an interesting phenomenon, worthy of much closer scrutiny. But it is not the subject of *The Politics of Nuclear Power*. Perhaps it should be, for the issues which crystallise around civil nuclear policy do not lend themselves easily to the conventional left-right of traditional party politics in Britain. However, Dave Elliott and his colleagues have here set themselves a more immediate task: that of persuading trade union members, and others on the left of the political spectrum, that it is in their interest to re-appraise official union policies which presently support civil nuclear expansion. Elliott and his colleagues can point to France, where the Confédération Française Démocratique du Travail (CFDT), the country's largest union, has played a leading role in attacking French government plans for headlong nuclear programmes; and to Australia, where the Australian Council of Trade Unions has been confronting the government for some four years, opposing official plans to mine and export uranium. However, it is also true that trade unions elsewhere—notably in the US and the Federal Republic of Germany—have been among the most enthusiastic and vehement proponents of civil nuclear activities. Even on a broader party-political basis the case is

by no means clear-cut. French and Japanese socialists, among others, are critical of nuclear power; but West German and Swedish Social Democratic governments have pressed ahead with nuclear expansion—only to find, in the Swedish case, a non-socialist party ousting the Social Democrats from office on a promise to phase out the nuclear programme. In the Soviet Union, of course, the civil nuclear programme has long had top priority, leading to the ironic spectacle late in 1978 of a party of American journalists, touring Soviet nuclear facilities under the auspices of the US Atomic Industrial Forum, champions of nuclear free enterprise. In short, the picture is confused, and confusing, and the time-honoured soapbox rhetoric of two-legs-good, four-legs-bad—or indeed *vice versa*—is unilluminating and unhelpful.

Fortunately, Elliott and his colleagues try to avoid sloganeering, concentrating on substantive factual information and analysis of particulars. An introduction by Elliott opens by declaring that "This book focuses on a number of problems, questions and issues relating to nuclear power likely to be of concern to workers in the nuclear industry and elsewhere". Elliott then offers a brief description of nuclear technology and its status in Britain and elsewhere. The main body of the book then falls into three sections: "The political economy of nuclear power", "Nuclear power and employment" and "Political strategies". Pat Coyne recounts the chequered history of British civil nuclear development, identifying what he calls a trend to "state corporatism" and concluding that "nuclear power in the UK has been developed and kept alive by a combination of political will and institutional inertia. Economically it has always been seen in terms of future needs rather than present benefits, and the arguments for its necessity are open to serious doubts . . . the consensus of political interest which previously sustained it shows signs of cracking". Mike George delineates the details of ownership and control of nuclear industry; and Elliott asks whether—given the industry's sorry economic record to date—central planners find nuclear power appealing because it lends itself well to centralisation. Elliott then discusses past attitudes to nuclear matters on the part of trade unions in Britain, through the TUC Fuel and Power Committee, who "simply ask for more of everything—coal, oil, gas and nuclear", and sees this attitude gradually changing, as "wider economic and employment issues are gradually beginning to be raised".

The NETWORK NATION **Human Communication via Computer**

Starr Roxanne Hiltz

Dept. of Sociology, Upsala College, East Orange, N.J.
**Murray Turoff, Computer Science Dept., New Jersey
Institute of Technology**

Foreword by **Suzanne Keller**, Department of Sociology,
Princeton University, and **Herbert R. J. Groch**, President,
Association for Computing Machinery, 1978-1978

During the next two decades, inexpensive computer
power and communication links will facilitate the
emergence of vast communication information networks.
"The Network Nation" is a comprehensive and
fascinating account of the nature of this new technology,
its present and future applications, and its impact upon
individuals and society.

ANALYZING QUALITATIVE/ CATEGORICAL DATA **Log-Linear Models and Latent Structure Analysis**

Leo A. Goodman, University of Chicago

With contributions by **James A. Davis**, Harvard
University, and **Jay Magidson**, ABT Associates Inc.,
Editor

Social scientists from sociology, demography, statistics,
education, market research, psychology, economics,
political science, evaluation research, as well as survey
researchers, methodologists, and statisticians who
analyze qualitative data, will be especially interested in
acquiring the tools described and illustrated in *Analyzing
Qualitative Categorical Data*. It is suitable as a text or
supplementary text for graduate or advanced
undergraduate courses in sociology, statistics, education,
market research, psychology, economics, political
science, and other areas in the social sciences.

1978, 460 pp., illus. 7" x 10"

ENERGY CONVERSION ENGINEERING

**Richard C. Bailie, West Virginia University and Environmental
Energy Engineering, Inc., Morgantown, West Virginia**

Foreword by Series Editors, **C. Y. Wen**, West Virginia
University, and **E. Stanley Lee**, Kansas State University

"... presents the fundamental background material needed
to understand the basic principles involved in energy con-
version systems. The book also serves as an introduction to
much of the material that will be appearing in subsequent
volumes of the Series. In addition, *Energy Conversion
Engineering* provides an excellent review for scientists and
engineers who are either entering into or redirecting their
activities to the area of energy science and technology."

From the Editors' Preface

Contents: Energy Uses and Resources. Thermodynamics.
Chemical Reaction Equilibrium and Kinetics. Combustion
of Fossil Fuel for Heat and Power. Coal Gasification and
Liquefaction. Nuclear Energy. Solar Energy. Environmental
Considerations. Economics, Politics and Social Implications.
Appendices. (Problems at the end of each chapter). Index.

1978 (November), 556 pp., illus. Hardbound 0-201-00840-8 \$19.50

TAYLOR & FRANCIS LTD. New and Forthcoming Titles

WILDLIFE MANAGEMENT IN SAVANNAH WOODLANDS

S.S. Ajayi and L.B. Halstead

Wildlife management in West Africa is being developed primarily to ensure the rational exploitation of the region's natural resources. This book contains twenty-eight papers presented at the first International Symposium on Wildlife Management, held in Ibadan, Nigeria.

238pp 229 x 152mm £12.00
Cloth 0 86068 176 7 January 1979

DRUG TOXICITY

J.W. Gorrod

This volume presents a broad-based text on drug toxicity and points to the direction in which toxicology is now moving. The increasing exposure to small amounts of chemicals in the environment and in food and drink takes the implications of much of this material far beyond drugs.

340pp 229 x 152mm £12.50
Cloth 0 86068 179 X March 1979

EDUCATION IN SYSTEMS SCIENCE

B.A. Bayraktar et al.

This NATO Advanced Research Institute report examines educational needs in Systems Science, evaluating past experience and the way present needs are served and looks to ways of responding to future developments.

394pp 234 x 156mm £12.00
Cloth 0 86068 182 X April 1979

MANUFACTURING SYSTEMS ENGINEERING

A unified approach to manufacturing technology and production management K. Hitomi

As a reference work for practising engineers and a text-book for engineering students, this book brings together the whole field of manufacturing systems engineering.

324pp 229 x 152mm £14.00
Cloth 0 86068 177 3 April 1979

SATISFACTIONS IN WORK DESIGN

Ergonomics and other approaches

R.G. Sell and P. Shipley

This is a practical book, discussing the relationship between the client and the consultant. The emphasis is on actual situations, including industrial case studies, performance, absence, turnover and sickness.

220pp 229 x 152mm £10.50
Cloth 0 86068 180 3 April 1979

ATOMIC AND MOLECULAR COLLISIONS

Sir Harrie Massey

Modern developments in technique have made possible an understanding in depth at the atomic level of the events occurring during collisions, and have provided data applicable to many branches of physics. This book provides a thorough introduction to the principles and applications of collision process studies.

320pp 229 x 152mm £12.00
Cloth 0 86068 144 7 June 1979

THE WYKEHAM SCIENCE SERIES

RADIOACTIVITY

A science in its historical and social context

E.N. Jenkins

This book surveys the development and applications of radioactivity. In addition to covering the science of this subject, it also provides an objective background to the nuclear power debate.

197pp 216 x 139mm £4.75
Paper 0 86109 730 9 January 1979

RADIOCHEMISTRY Theory and experiment

T.A.H. Preece

Radioactivity is explained in relation to chemistry and its applications. Early experiments, the laws of radioactivity and techniques for detecting and measuring radiations are given an exact and quantitative treatment, in a book emphasizing the experimental approach to science.

274pp 216 x 139mm £4.95
Paper 0 86109 690 5 January 1979

MAN-MADE DISASTERS

B.A. Turner

Some of the common features of accident situations — the types of social defect and human error involved — are discussed in this book, both in general and in relation to certain specific disasters which have been thoroughly analysed.

254pp 216 x 139mm £5.00
Paper 0 86109 750 2 January 1979

SEX DETERMINATION AND SEXUAL DIMORPHISM IN MAMMALS

A. Glucksmann

This monograph draws attention to the many variations with gender in the 'normal' structure and function of mammalian organs, and their bearing on the reactions to exogenous influences and points to directions where further research is needed.

192pp 216 x 139mm £4.75
Paper 0 86109 790 1 January 1979

SOLAR ENERGY

J.I.B. Wilson

The principles behind the interaction of light with matter and of energy conversion are reviewed. The book not only covers the mechanical aspects of solar energy conversion, but also the physical principles involved in collecting solar radiation and the use of solar and photochemical cells.

190pp approx. 216 x 139mm £4.50 approx.
Paper 0 86109 810 X Autumn 1979

ULTRASONICS

A.P. Cracknell

This book is concerned with the basic physics of the generation, transmission, attenuation and detection of ultrasound. Ultrasound's main applications and its occurrence in nature are described. New areas for use are explored and there is a discussion on safety in the use of ultrasound.

190pp approx. 216 x 139mm £4.50 approx.
Paper 0 86109 770 7 Autumn 1979

SIPRI Publications

(Stockholm International Peace Research Institute)

ANTI-PERSONNEL WEAPONS

On the eve of a UN conference on Weapons which are inhumane or cause unnecessary suffering, this volume surveys the progress of conventional weapons, from those used in World War II to the more recent products of science, including napalm, cluster bombs and similar fragmentation munitions and high velocity bullets which break up inside the body.

200pp 240 x 174mm £9.00
Cloth 0 86068 128 5 January 1979

POSTURES FOR NON-PROLIFERATION

Arms limitation and security policies to minimize nuclear proliferation

This book aims to identify a set of policies to be undertaken by the major states for long-term arms limitation, which will satisfy the security and political objectives of the non-nuclear weapon states. The Non-Proliferation Treaty and subsequent developments are reviewed.

168pp 240 x 174mm £6.50
Cloth 0 86068 133 1 May 1979

WORLD ARMAMENTS AND DISARMAMENT

SIPRI Yearbook 1979

The tenth SIPRI Yearbook continues the analysis of the world arms race and the attempts to stop it. Throughout, detailed information on developments to the end of 1978 is given, with the aid of numerous tables.

720pp 240 x 174mm £21.50

cusses health and safety and trade unions rights in the nuclear industry, and points to the need for more information. Consideration is then given to jobs, energy and industrial strategy, and alternative policy options of the kind recently detailed by Gerald Leach *et al.* in their report *A Low Energy Strategy for the UK* (Science Reviews Ltd and IIED: London, £7.50; for review, see *Nature* 277, 162; 1979). According to Elliott, "Because the alternative technologies are mainly, by their nature, decentralised they can support a decentralised society, based on community and workers' control. But their introduction into society as it is clearly doesn't necessarily guarantee that such a state of affairs will come about". However, Elliott concludes, "The fight for alternative technologies is not an alternative to the fight for socialism. It can and should be part of it"—a sentiment making up in vigour what it lacks in grace. Part three of the book discusses how such aims can be pursued, by trade unionists and environmentalists working for common objectives.

All four authors write clear, readable prose, in language which is accessible

and blessedly low in jargon. However, it is a pity that more attention was not paid to fine detail; too many trifling but irritating errors of fact have survived into print. (There are eleven British Magnox stations in all, not twelve, including a total of 26 reactors; there is no power reactor in Denmark, only three small research reactors; Belgium, far from being a nuclear "poor relation", has three substantial power reactors already in operation and four more under construction, and generates a larger percentage of its electricity by nuclear power than any other country; the proposed commercial fast reactor would be 1,000 MW, not 100 MW; and so on.) It would be easy to correct virtually all these fluffs in a second printing. To do so would remove the most irksome blemish on what is otherwise a very useful book, one which deserves to be widely read and discussed, by trade unionists, environmentalists, and all those other 'ists who make up our disputatious society. □

Walt Patterson is Energy Consultant to Friends of the Earth (London) Ltd.

Peer review in the NSF

S. S. Blume

Peer Review in the National Science Foundation: Phase One of a Study. By the National Research Council. Pp. 193. (National Academy of Sciences: Washington, DC, 1978.) \$10.75.

Most readers of *Nature* will be well aware that the peer review system (the system by which research grant applications are evaluated by experts in the disciplines concerned) has recently been subjected to considerable criticism in the USA. Members of the general public as well as congressmen have attacked an 'old boy network' said to have control of research funds. The National Science Foundation has steadfastly refused to make confidential referees' reports (and their names) available to members of congress, and this has been held to be a concealment of the Foundation's biased procedures. Politicians have also accused the Foundation of giving inadequate weight to the needs of society (as distinct from those of science) in the selection of projects for funding, and

of discriminating against scientists in less prestigious institutions. The fault, some claim, lies in the peer review system. Ripples of these criticisms—the view that justice should not only be done but be seen to be done, that criteria of equity applicable in other areas of public resource-allocation should apply also in science—have reached these shores. For example, not long ago the UK Research Councils had to consider the claim that they dealt unfairly with scientists working in polytechnics.

This volume reports on the first stage of a study of the operation of the peer review system in the NSF, commissioned by the National Academy of Sciences. The researchers were given full access to reports and files on all applications to the Foundation. They interviewed programme directors (who unlike British committee secretaries have final responsibility for deciding which applications in their field get funded). In the study the authors focus particularly upon three things: How are reviewers (referees) chosen? How do the referees respond to various characteristics of the applicant other than their assessment of the quality of his (very rarely her!) application? And how does the final decision (that is, of the programme director) relate to the referees' assessments?

The study provides no ammunition to the critics of science. An effective combination of statistical and qualitative analysis is used to show, most

simply, that the best research gets funded. No evidence for an old boy network is uncovered, and findings suggest that referees are not much influenced by the status of the applicant's institutional affiliation, or by his seniority, or by whether he has or has not recently had a Foundation grant. They simply judge the application on its merits. Moreover, it seems to be these evaluations which do largely determine what gets funded. To be sure, if one tabulates 'successful' compared with 'unsuccessful' applications by extraneous variables such as those suggested above, one finds clear differences. But all of these vanish when reviewer's evaluation is introduced. Of course there are curiosities. A not infrequent one seems to be the eminent scientist whose application is rejected because it consists of little more than "I'm me—give me the money"! So the system seems to work as intended, and this study shows this to be so.

Nevertheless, as I am sure both authors and sponsors appreciate, the study will not silence the critics. It is not simply that the 'enemies' of science are unsusceptible to reason (though one wouldn't really expect them to succumb to a piece of applied social research). It is also because the study does not—perhaps could not—tackle all the criticisms made. For example, referees are required by the NSF to consider an application in the light of criteria reflecting the competence of the investigator, the scientific merit of the project, its relevance and utility, and its broad implications for American science and science education. The brief section of the report devoted to the problem of weighting these considerations against each other is all too sketchy, and will hardly persuade the cynic that much attention is paid to questions of practical applicability. One gets no feel for this at all. The critic can still claim that if the scientist from a poor southern college is 'fairly' treated, that is not enough. After all, positive discrimination in favour of the disadvantaged is an accepted feature of many areas of policy—why not in science? And even the favourably disposed but budget-conscious politician may feel uneasy in defending a government agency which makes "no systematic attempt to monitor the outcomes of research grants" (p. 158)—that is, to see how its money was spent.

But perhaps for the reviewer to attack a methodical piece of research for failing to resolve an essentially political dispute is not only naive, but inappropriately partisan. □

Stuart Blume is in the Department of Social Science and Administration, London School of Economics, University of London, UK.

Tribology textbook

Robert Schnurmann

History of Tribology. By D. Dowson. Pp. 677. (Longman: London and New York, 1978.) £35.

IN 1964, the Rt Hon. the Lord Bowden of Chesterfield as Minister of State for Education and Science had asked Mr H. Peter Jost to set up a working party to report on lubrication research and teaching requirements. The academic world was represented on this working party by Professor Dowson. Before its findings were published in February, 1966, the "Jost Committee" had asked the editor of the Oxford Dictionary for a "pithy name to summarise in one word the closely related subjects of Friction between Solid Bodies, Wear, and Lubrication, and he suggested 'Tribology'. Thus, HMSO published the report of the working party under the title *Lubrication (Tribology), Education and Research—A Report on the Present Position and Industry's Needs* which specifically mentioned "a conservative estimate" of the potential annual savings to British industry from improvements in education and research of "about £515 million, the biggest single item being savings in maintenance and replacement costs of £230 million".

This triggered off a spate of activity. Three centres of tribology were established in this country, two at Universities (Leeds and Swansea) and one in a government establishment (Risley). Tribology committees were formed, both national and international. Later, the Institution of Mechanical Engineers, which had already sponsored in 1937 a "General Discussion on Lubrication and Lubricants" and had followed this up twenty years later by another conference on "Lubrication and Wear" (organised jointly with the American Society of Mechanical Engineers), set up a Tribology Trust which has made annual awards (gold, silver and bronze medals) since 1972. Also in 1966, a news sheet called *Tribology News* was launched. A flood of publications and conferences was unleashed. 'Tribology' had arrived.

In 1969, Professor Dowson, who is the founder and director of the Institute of Tribology in the University of Leeds, decided to write a textbook on the subject with an opening chapter on its history. This 'chapter' grew to become the present book of 677 pages.

Looked at in a down to earth man-

ner, friction between solid bodies can either be unlubricated or lubricated, and in the latter case it depends on the operating conditions whether the film of lubricant is thick enough to sustain hydrodynamic lubrication—also called 'thick-film' lubrication—or whether one has to consider 'thin-film' lubrication—where the film of lubricant is not thick enough to allow of hydrodynamic flow. The word 'dry', in connection with unlubricated friction should only be used within inverted commas, because the surfaces of all solid bodies carry layers of one contaminant or another, either oxides or sulphides, or adsorbed or condensed matter. Even if these were removed by volatilisation in an ultra-high vacuum, recontamination of the surfaces, which were made 'naked' by volatilisation, would commence instantaneously.

The case is not analogous to the experiments of Agnes Pockels and Irving Langmuir, who scraped and thereby created a 'naked' water surface simultaneously with the application of an organic liquid. This is not the way in which Professor Dowson has set the scene. He would probably agree, however, that friction between solid bodies is a very complex phenomenon. The 'Jost Committee' rightly said that it is "multi-disciplinary". This has been very little heeded in the literature to which Professor Dowson refers. Even when he approaches the end of his journey through the ages and turns to his own subject of Bio-tribology, he uses the misleading word "cold-welding" for what is in fact the adhesive action of films so extremely thin that internal shear in these films is no longer possible (Lord Rayleigh's celebrated 'cup and saucer' experiment).

Throughout the book there is a great deal of confusion between adhesion and cohesion. The wide use of Johansson thickness gauges does certainly not support Professor Dowson's claim of the "cold-welding" of like metals, within the true meaning of the term 'welding' as an interpenetration of crystal grains. True, each gauge block is coated with lanolin before they are wrung together, but the process of wringing them together is necessary to make the residual film thin enough for strong adhesion. In this context, Amontons (p154) had coated his blocks of either copper, or iron, or lead, or wood with cart grease, not necessarily with "old pork fat". Amontons himself said "... enduits de vieux-oint". The other blocks "of similar materials and different sizes" which were loaded against the greased ones were ungreaed. Nowhere is there any mention of the significance of Amontons' Law as a wear criterion and its importance for the safe operation of machinery.

Neither is it Professor Dowson's thesis that it now seems that Sir William Hardy's introduction of the term 'boundary lubrication' was perhaps unfortunate, particularly if it is used to differentiate qualitatively between materials which function by the same mechanism though with marked quantitative differences, such as additives for so-called 'boundary lubricants' and additives for 'extreme pressure lubricants'. Similarly, referring to the chapter on wear, the important qualitative difference is between "mild wear" and "catastrophic wear" and not between "adhesive" and "abrasive wear".

Professor Dowson has included in his account 16 pages of history of the petroleum industry and of the origins of the major oil companies. John D. Rockefeller was indeed a dominant figure for the greater part of his life. He became a philanthropist at the end of his business career, and for many years, the Rockefeller Foundation did a great deal for the promotion of some outstanding scientific research by enabling promising young scientists to spend one year's leave of absence working with people, such as Lord Rutherford, Niels Bohr, Enrico Fermi, Otto Stern, to name but a few.

The petroleum industry discontinued some years ago the use of 'a-hole-in-a-pot' viscometers, such as the Redwood, or Saybolt, or Engler, and nowadays uses glass capillary viscometers. Incidentally, the c-g-s unit of kinematic viscosity is "one Stokes" and not "one stoke". The SAE classification of lubricating oils concerns their viscosity levels and has nothing to do with the dependence of their viscosity on temperature. Even Dean and Davis's 'viscosity index' (VI) only compares the viscosity-temperature dependence of a lubricating oil with that of two other lubricating oils, one of which is a Pennsylvanian oil which has a comparatively very flat viscosity-temperature curve, whereas the other one is a Gulf Coast oil which has a relatively very steep viscosity-temperature curve. Therefore, the VI-numbers assigned to these two types of comparison oils were arbitrarily taken as respectively 100 and 0. This was an important marketing asset in the days when only one of the American oil companies had a monopoly on Pennsylvanian Brightstock, which was added to petroleum distillation cuts and raffinates as a VI-improver. With the advent of mineral oil-soluble polymers, values of VI greater than 100 could be attained, and the Dean and Davis scale cannot be used here. For these values of VI above 100, W. A. Wright constructed a different VI-scale. The *Standard Methods of Testing Petroleum and its Products* of the Institute of Petroleum, the American Society for Testing Ma-

terials, and ISO have therefore given since 1966 "two procedures" for calculating VI, one for values between 0 and 100 and, if calculation should indicate a higher value, another one for values above 100.

Professor Dowson explains in his introductory chapter the chronological "Structure of the book", which is divided into 11 chapters, and his belief in "the wisdom of the 50-year rule", in connection with chapter 11 which has the heading: "Towards tribology: 1925—the present". The "50-year rule" is Professor Dowson's own variation on someone else's comment that "... a wise historian usually stops 20-30 years before his own time, because he cannot see the wood for the trees; the so-called thirty-year rule". The book has an appendix of 25 biographical sketches which were modelled on a book by one F. R. Archibald.

The book is remarkably free from misprints. There are the odd ones, but they are few and far between, although it is a little startling to find on p443, for instance, -11.8°C as the conversion of 0°F , when the right figure of -17.8°C is given 5 lines further down; that 121.1°F is given on p30 instead of 119.1°F as the conversion of 49.5°C is less easily explained; nor that 0.001 oz is said to be equal to 0.038 g, whichever kind of ounce it may be. But these are details. What is disturbing are the many mistakes both in the body of the text and in the "chronological tables".

Bourgeois chemist

Colin A. Russell

Gay-Lussac: Scientist and Bourgeois. By Maurice P. Crosland. Pp. 333. (Cambridge University Press: Cambridge, 1978.) £15.

DECEMBER, 1978, was a busy one for chemical historians. The bicentenary celebrations of Humphry Davy's birth were followed by similar festivities in honour of the French chemist, Joseph Louis Gay-Lussac. Both men were born in December, 1778, though in the country of his birth Davy is much better known. Although equally distinguished for his chemical work, Gay-Lussac has had to wait until his bicentenary for a full length biographical treatment in English. The urgent need for such a book has now been met by the timely appearance of this study by Professor Maurice Crosland.

To most modern chemists, Gay-Lussac is merely a name associated

This is not the time and place to list them all. A few randomly chosen examples must suffice here. Lord Rutherford discovered the atomic nucleus in 1911. In 1919 has great achievement was the 'splitting of the atom'. He coined the name 'proton' for the positive hydrogen ion because, before the discovery of the neutron in 1932, he considered protons and electrons to be the elementary particles of the atomic nucleus. C. T. R. Wilson's cloud chamber dates from 1897; and 1926, not 1924, is the date for Schrödinger's wave mechanics. The name of the discoverer of X-rays was Wilhelm Conrad Röntgen and not "Wilhelm von Röntgen". Sir William Hardy and Philip Bowden were members of the Senior Common Room of the same Cambridge College, Gonville and Caius. The chronological tables are not without their own mysteries. In the juxtaposition of "Political and social events", "General, technical and scientific developments", and "Tribology", one wonders why the "Tribology" column was chosen to record such events as Henry Deterding assuming "control of Royal Dutch Company", the "merger between Royal Dutch and Shell", and the move of the Timken Company to Canton, Ohio. □

Robert Schnurmann is Honorary Research Fellow in the Department of Chemical Engineering at the University of Birmingham, UK.

with two or at the most three notable achievements, the best known of which is his Law of Combining Volumes (1808), asserting a simple ratio between volumes of combining gases and their products (if gaseous). He has also been associated with the law connecting gaseous volume with temperature, though more frequently this is referred to as "Charles' Law"; in fact Gay-Lussac was the first to publish (1802), but his experiments were based on earlier work by J. A. C. Charles. Thirdly, chemists will recall the "Gay-Lussac tower" as part of the lead chamber process for making sulphuric acid, being a device for recovering nitrogen oxides from the effluent gas. The last Gay-Lussac tower that I know of in this country disappeared when the final lead chamber plant was dismantled about four years ago, so a further association with Gay-Lussac will be lost to future chemists.

However, as Crosland has been at pains to show, Gay-Lussac is worthy of commemoration for much more than this. His Law of Gaseous Volumes not only provided the foundation on which Avogadro and Cannizzaro were later to build their own theoretical structures; it seems that it confirmed to its

discoverer the fundamental importance of volume measurements—even greater than that of weights. This conviction was nurtured by Gay-Lussac's respect for his mentors Berthollet and Laplace, whose concern for establishing general laws in science proved more attractive to their young disciple than the mere multiplication of new compounds, rather in the old natural history tradition. Oddly enough, recognition of the Law seems to have been unexpected and came (as did many other generalisations in nineteenth-century chemistry) from studies of relatively obscure and complex phenomena, in this case the reaction between ammonia and boron trifluoride.

Associated with Gay-Lussac's work on gaseous volumes was his recognition of vapour densities as accessible and significant parameters for a compound. They were prominent in his researches on the new substance iodine. Gay-Lussac studied it extensively, concluding it to be an element similar to chlorine. He described and analysed hydrogen iodide, and discovered iodic acid, two chlorides of iodine, iodoethane, and so on. Closely related to this work was his research on cyanides. He obtained "prussic acid" in a pure state and prepared cyanogen for the first time. Wavering in his patriotic devotion to the memory of Lavoisier he recognised that oxygen need not always be present in acids, and to cover hydrogen halides and cyanide introduced the term "hydracid".

Nor was Gay-Lussac's concern with volumes confined to gases. In a largely industrial context he pioneered analytical methods for solutions. To have "introduced scientific rigour and established volumetric analysis as a branch of chemistry" was no mean achievement. By fitting a vertical side-tube to a graduated cylinder he devised a primitive burette that may still be occasionally encountered (though it soon turned out to be too fragile for the industrial purposes for which it was designed). He developed the pipette to something like its present form, introduced arsenic (III) as a standard for chlorimetry and made many further innovations. Other scientific work ranged from a study of fermentation to the development of lightning conductors. He studied meteorology and heat, and became one of the few Frenchmen to follow up the discovery of the Voltaic pile.

Gay-Lussac's chemical research is described in this book with verve and skill. The historian will delight in the clarity with which arguments are marshalled and the degree of historical analysis that enables his work to be seen within the context of contemporary science. Chemists will welcome a historical account that actually takes

the trouble to describe the chemistry being done—an increasing rarity these days. They may cavil at a nomenclature that sometimes is neither ancient nor modern and at the use of "react" as a transitive verb, but these are small blemishes in an account that takes seriously the scientific content of Gay-Lussac's lifework.

Gay-Lussac

For all his obvious sympathy and respect for Gay-Lussac, the author does not portray him as either saint or hero. Rather charmingly he includes in the index an entry "Gay-Lussac, Joseph Louis, mistakes of"! It has five references. Rightly he does not classify the rejection of atomism as a "mistake", though with hindsight it might be said to have been a pity. In Gay-Lussac's thinking there was a streak of pre-Comtean positivism later to find fuller expression in the uncompromising anti-atomism of Berthelot. This reluctance to go beyond experimental data taken in conjunction with Gay-Lussac's predilection for general laws suggests a tension which is never completely resolved.

Gay-Lussac is presented as a product of the middle classes determined at very least to maintain his social position. This resolve seems to have been a mainspring for his lifework, leading him to accept a plurality of academic posts, to develop his consultancy practice and to do all he could to improve his financial position. Two bar-charts illustrate that as his productivity (in terms of scientific papers) declined, so his salaried income rose to a peak. It is interesting to contemplate this recipient of a 50,000 Fr. salary insisting on patent rights for his

"Gay-Lussac tower" (and receiving 150,000 Fr. as his reward), while a self-taught plumber on Tyneside declined to patent the very device that made the Frenchman's invention a practical proposition—the "Glover tower". However some may wonder whether financial gain was all that being a "bourgeois" meant for Gay-Lussac's science. Did "bourgeois" attitudes colour the solution as well as the selection of scientific problems? Was his commitment to laws of nature (for instance) a reflection of middle-class convictions about the world? On these matters the author says little, probably for the good reason that there is little that can be said with any confidence, although he does allude to Gay-Lussac's ambivalent attitude to metrication, when "bourgeois" and "scientific" values were in conflict. He also gives a brief account of the chemist's activities as a Member of the Chamber of Deputies and his typically protectionist attitudes to industry and (especially) agriculture.

Gay-Lussac's institutional affiliations give his biography special interest for historians. He held posts in the Ecole Polytechnique, the Paris Faculty of Science, the Muséum d'Histoire Naturelle and the Ecole d'Application des Tabacs; he was a member of the National Institute and of innumerable official committees; he was joint editor of *Annales de chimie et de physique*; he became assay master of the Mint and was closely associated with the chemical plant of the great Saint-Gobain Company; above all, his early years were spent in the unofficial scientific society that met at Berthollet's home at Arceuil. Such a wealth of association gives the author an opportunity to place his subject in an institutional context of extraordinary breadth, and this he does remarkably well. Quite apart from the importance of Gay-Lussac himself, this biography gives a valuable insight into French scientific institutions of the early nineteenth century. Because of Gay-Lussac's specialist training in science, and because he subsequently earned his living through its practice, Crosland regards him as "one of the first generation of professional scientists". One wonders how useful a category of analysis this may be for an individual in early nineteenth century France, in view of the ambiguities lurking within the concept of 'professionalisation'. It may suggest false analogies between different countries or different periods. Only when such a term is rigorously defined does it become meaningful, and precisely at that moment it becomes redundant. If professionalisation is seen at the time to be a crucial issue then that of course is a different

developmental genetics

volume 1 • 1979 • four issues

This new journal is devoted to the study of gene expression, during development and differentiation, in biological systems. The primary emphasis is on the molecular, biochemical, and physiological aspects of gene action and regulation during development.

Developmental Genetics publishes full-length articles describing original experimental research on gene action, interaction, and regulation as related to developmental processes, irrespective of organisms; interactions between genotypes in sexual and parasexual hybrids with regard to developmental processes; interactions between genotypes and developmental stimuli, including normal and experimentally manipulated systems; and other related areas. The journal also occasionally publishes reviews of timely topics.

Oxygen in the Metal and Gaseous Fuel Industries

The first of a series of triennial Priestley Conferences held at Leeds in September 1977, was structured to mark the important contribution made by heterogeneous oxidation to the iron, steel, and non-ferrous metal industries and to the production of gaseous fuels. It brought plenary lectures from Australia, Austria, and the USA, as well as from the UK, and all ten lectures are brought together in this book to provide a unique record of the major part that oxygen plays today in our metal and energy industries.

Brief Contents:

Priestley Lecture: Science and Education; Oxygen Today and Tomorrow; Oxygen in Iron and Steel Production; The Use of Oxygen in the LD Process for Steel Production; Oxygen in Substitute Natural Gas Manufacture (in UK and USA); How Oxygen Molecules Gasify Carbons; The Combustion of Carbon; Developments in Oxygen Smelting; Oxygen in Hydrometallurgical Processes for Winning Metals; Oxygen — The Good and Bad Performer in Welding.

matter, but this does not seem to have been the case with Gay-Lussac.

The author declares "this biography will help give flesh and bones to one of the names found in science textbooks but, in so doing, it may also make a small contribution to a fuller understanding of the development of science". I believe that he is both over-sanguine and too modest. For me, at least, Gay-Lussac never emerges as a rounded human personality. Here and there we catch glimpses of a somewhat unbending autocrat tending to inspire respect rather than affection and himself under pressure from a financially ambitious wife. But in fact we learn little of his family life, his hobbies ("no great interest in the arts") or his religion (Enlightenment humanism). We do not even know the circumstances of his death. On the

other hand, for science itself the book makes more than the "small contribution" suggested by the author. It is a solid piece of research meticulously executed with tables, footnotes, bibliographies, appendix and indexes, and is a substantial addition to our understanding of the development of chemistry at an important stage of its history. At £15 one might have expected the publishers to allow the author more illustrations than the solitary portrait that appears as the frontispiece. But we must be grateful to Gay-Lussac for having contributed so much to chemical science and to Maurice Crosland for an illuminating and soundly-constructed essay in scientific biography. □

Salt in perspective

Frank Greenaway

Neptune's Gift: A History of Common Salt. By R. P. Multhau. Pp. 325. (Johns Hopkins University Press: Baltimore and London, 1978.) £15.75.

"SALT was known to the Ancients". So began for fifty years the lectures on the halogens given by an imperishable Oxford don. Robert Multhau might well have begun his excellent book with the same words, conveying as they do the antiquity and continuity of his subject. A book which is primarily historical in intent, but concludes with a reference dated 1976 is, to say the least, unusual, but Multhau is an unusual man.

He has been a man of action and saw the world before entering on a career at the Museum of History and Technology at the Smithsonian Institution which made him so well known as a leading historian of chemistry. His reach is long and his grasp firm. This work on salt has all the fluency and density of significant detail which make his earlier work *The Origins of Chemistry* so valuable.

The book falls into two main sections: "The Age of Culinary Salt" and "The Era of Chemical Salt". The transition is set later than would seem obvious—that is, in the nineteenth rather than the seventeenth century. Multhau sees the food preservative role of salt as its more important feature well into the nineteenth century. Only with the expansion of the

chemical industry as a whole and the concomitant expansion of large-scale manufacturing industry and long distance bulk transport does he depict salt as a key chemical raw material.

Salt is a universal necessity. Without an adequate intake, direct or indirect, normal health cannot be maintained. Yet salt is not so widespread a natural substance as might seem from its invariable association with animal life. It has to be sought by human and animal alike; so since ancient times, it has had the scarcity value which makes for trading and taxation. A history of administration could be written around salt, "an ideal article for fiscal management". There was a universal demand for it, its supply could not be left to chance and it was a fairly easy commodity to control, as was found not only in Europe but also in China and elsewhere. The salt tax, the *gabelle*, was hated in France and seems to have been one of the precipitating causes of the French Revolution. However, one must not take too simple a view of the historic role of salt taxes, which came and went in a very irregular way in the United States, and were much confused in Indian history by the close relationship of salt with the important saltpetre industry and trade.

The extraction of salt is an exceptional example of the stability and continuous survival of techniques which, though crude and simple, were efficient enough to render modification unnecessary for centuries. There were several methods, some of which might be found in use within a short distance of each other: evaporation of seawater by fire or solar heat, surface mining, deep mining, leaching, and so on. Simple pottery pans for boiling down brine were so customary that their fragmentary remains are good evidence of the

existence of a salt industry. The largest salt industries, however, were eventually those based on deep-mined rock-salt, the demand being that of the new chemical industries. (One of several sections contributing to the wider history of technology is that dealing with drilling.)

Before salt entered its modern phase of being the raw material for sodium compounds and for chlorine, it was one of the most important means of sheer survival, being an invaluable food preservative. Lynn White has drawn attention to the importance of improved second-class protein supplies to the development of mediaeval technical vigour, but the argument can be continued: new technical improvements in salt manufacture improved the availability of meat and fish protein and so progressively helped to bring about the energising of Western Europe which ushered in what we can still usefully call Modern Times. But even greater expansion was to come as salt-mining benefited from the steam-engine and the development of iron machinery. Multhau uses an enlightening analogy: comparing early salt-mining to an agricultural pursuit because of its often seasonal character, and showing how it was transformed into a non-seasonal industry. By 1850 the alkali industry took up about a third of British salt production. In the United States, the new meat-packing industry called for a great deal, but industrialised food preservation was much less important elsewhere. Direct culinary use levelled off about 1850, using about half of the British total at that time. The industry expanded, however, and the second half of the book explains why. The nineteenth-century chemical industry had soda as one of its pillars with salt as the base, and the vast increase in the use of salt-derived chlorine in solvents, plastics, pesticides and the like. Multhau points out how in the case of salt, as with so many other substances, the dominant industry is the automobile industry, using the plastics and solvents, which need chlorine, in direct manufacture, but also using very large amounts of salt as such for road treatment in winter.

The book is well produced, particularly well documented, and equipped with valuable maps and statistical tables.

Salt was known to the ancients, but, in spite of its importance, is little considered today in the perennial discussion of the effects of technology. *Neptune's Gift* should do much to equip us to see it in its correct perspective. □

Shifting paradigms in chemistry

Maurice Crosland

Chemistry Transformed: The Paradigmatic Shift from Phlogiston to Oxygen. By H. Gilman McCann. Pp. 179. (Ablex: Norwood, New Jersey, 1978.) \$14.95.

THIS book is in many ways a pioneering study. Using T. S. Kuhn's idea of 'scientific revolutions' Dr McCann has spent more than ten years analysing one particular case. It is comparatively easy for the non-specialist to understand the main features of the so-called 'Chemical Revolution' of the eighteenth century, and a succession of philosophers of science have used it to illustrate their views about theories, falsification, and so on. This is the first time that a sociologist of science has tackled this historical question and we must respect the author's study of the relevant chemical journals and a wide range of secondary literature. This is no superficial survey but an attempt to achieve a better understanding of what really happened. The author also touches on the beginnings of the professionalisation of chemistry in France. With his great industry in statistical analysis of his data McCann deserves to succeed in saying something new and important. Certainly his approach opens up several interesting perspectives.

It is difficult to say exactly when Lavoisier's oxygen theory came to take the place of phlogiston. McCann marshals his data into periods: 1772-77 being the period during which Lavoisier was developing his theory and 1778-84 the years when Lavoisier was trying to justify his theory to others and meet their objections. 1785 was the year of Lavoisier's experiment on the composition of water which helped win over Berthollet, with other major chemists soon to follow. In Britain conversion to the new views was slower, and much ingenuity is exercised by the author to explain this. Rejecting nationalism as a possible ground, McCann believes that the British "chemical community" (if there was one) was more elderly than the French and therefore more conservative. Indeed the importance of age is claimed to be one of the great 'discoveries' of the quantitative sociological analysis used. But the author passes far too

easily from a plausible hypothesis about receptivity to one about innovation. It is claimed that what made Lavoisier unique was not (as has been assumed) his genius but his comparative youth, being only 29 at the time of his vital work which recognised the gain in weight of phosphorus on combustion. But what about other French chemists who were about the same age? One might mention the provincial chemists Cornette (28) or Opoix (27). Of course these did not have the advantage of living in Paris, of being members of the Academy, or of having a special interest in gases. But if age was so important in being open to change why is Lavoisier's exact contemporary Opoix remembered (if at all) as a late champion of the phlogiston theory?

Perhaps after all one needs to examine various other factors including

Antoine Lavoisier

Mary Evans Picture Library

the arguments used on both sides, an aspect glossed over in the sociological treatment. The superiority of the oxygen theory is assumed and it is never mentioned that this 'correct' theory whose acceptance we are analysing included the (incorrect) 'caloric'. This is particularly serious in so far as it affects the very concept of a 'paradigm shift' mentioned in the subtitle, as it has been suggested that in some ways 'caloric' was phlogiston under another name. On p96 there is a remark about "the period of crisis as the French chemists solved problems that stymied the phlogistonists of Britain" but there is no hint that the phlogistonists provided problems such as that of 'heavy inflammable air' which were insoluble in terms of the oxygen theory until Cruickshank in 1801 showed that this was carbon monoxide.

The attempt to gain new knowledge

by a quantitative approach is worth serious examination and it is a pity that this brave beginning is open to a wide range of objections, of which one is the small size of the sample used. Thus in the period 1778–80 one new author could write 20% of the articles cited. The problem of the disproportionate number of articles written by Lavoisier himself is fully appreciated by the author, who presents data in alternative forms to meet this objection. There is also the problem of biographical detail for some of the lesser well known chemists which might affect the picture of the 'average chemist'. Finally it is

not clear to the reviewer how we can count "oxygen articles" in journals before the discovery of oxygen.

I am sure that a careful use of a quantitative approach may provide valuable new insights in understanding the development of science but it will be all the more useful if it is brought in as an additional tool rather than as an alternative. In counting heads let us not ignore what was in those heads.

Maurice Crosland is Director of the Unit for the History, Philosophy and Social Studies of Science at the University of Kent at Canterbury, UK.

Respecting aberrant figures

J. R. Ravetz

Man and Nature in the Renaissance. By A. G. Debus. Pp. 159. (Cambridge University Press: Cambridge and London, 1978.) Hardback £7.95; paperback £2.50.

THE history of the science of the period of the Renaissance is directly relevant to the practice of science today, for our present ideas of what constitutes genuine science, and what demarcates it from false imitations, were forged then. For a very long time it had been common for historians to take the evaluations of the seventeenth-century innovators as simple fact: those who adhered to older methodologies of world-views were simply reactionaries, fools or charlatans. Scientists who achieved great science (by our standards) in spite of such defects (as Kepler or Gilbert) were explained as being "strange mixtures of the old and the new".

In recent decades, there has been a thin but growing stream of research

that treats some of the aberrant figures with respect, both for their stature in their own times and for such 'positive' achievements as can be gleaned from their work. The most promising candidates for such re-evaluation are in the tradition of alchemically tinged practical chemistry, relating directly to metallurgy, medicine, and having implications for philosophy, religion and politics. The leading figures in that 'chemical philosophy' were Paracelsus and van Helmont; its leading interpreters Page, Rattansi and Debus.

Now this school has produced an introductory textbook by which students are shown how much more there was to the scientific revolution than the developments centring on the work of Galileo. In it we find brief and illuminating accounts of the 'chemical philosophy'. Otherwise, it is a competent survey of developments in science and in methods in the sixteenth and early seventeenth centuries. As it is read and used, we may expect that the 'chemical philosophy' will achieve a sort of respectability among those who learn or teach the history of science.

This is a very valuable achievement. A most urgent educational task is to show that the Galilean style of reductionist, abstracted research is not the uniquely true approach to a proper knowledge and control of nature. A modest and uncontroversial introduction to a broader conception of science

will have a greater diffusion in teaching establishments than a strident polemical tract. But a price is paid for this very Fabian approach to intellectual reform; there is a loss, not so much of ideological militancy as of historical drama. Our sort of science was conceived and propagated by men with a prophetic mission. The issues in their debates ranged over all human values and experience. Different conceptions of reality were in open collision then, and ideological commitments (based on a fusion of political and theological concerns) could be as important as experimental facts in determining positions in the still immature natural sciences of the time. Of all this, we get only the most mild of hints. The received historical doctrine of the rise of modern science as an automatic consequence of the adoption of correct attitudes and methods, is here not so much challenged as modified at the fringe. But perhaps that is appropriate for a pioneering venture in textbook writing; and as a simple, lucid and accessible introduction to its subject, the book succeeds well. □

Wheelwrights of the heavens

A. W. Sleeswyk

Geared to the Stars: The Evolution of Planetariums, Orreries and Astronomical Clocks. By H. C. King, in collaboration with J. R. Milburn. Pp. 442. (Adam Hilger: Bristol, 1978.) £25.

IN twenty-one chapters and over 366 pages, illustrated with 333 diagrams, reproductions of engravings and photographs, sprinkled with 2,236 footnotes, this book gives an account of planetariums, telluriums, orreries, globe clocks, astrolabes, lunariums, astronomical clocks, equatoriums, satellitians, cometariums; all of them, to the modern eye mechanical analogue computers of the Solar System, but differing in the way the data are displayed. These models—often of great beauty—are now, as are all analogue computers, being superseded. At the end of the book the most modern planetarium is described, with the heavenly bodies represented by spots of light projected on the interior of a dome vaulting over the audience, and controlled by a digital mini-computer.

Astronomers, who often earned their keep as astrologers, have observed from the earliest times onward the recurrent motions of the heavens, and the bodies moving in them—Sun, Moon and planets. Whether or not awed by “the infinity of those spaces”, they determined with ever-increasing accuracy the different periods of these motions, whose ratios are never exactly expressible as finite quotients. Hence the challenge to clever craftsmen to produce close approximations by ingenious gearing.

The material is arranged in a roughly chronological order, starting with the little we know about Hipparchos and Archimedes in connection with astronomical models—the protohistory of the subject. Under-water archaeology brought to light the next item, the astonishing Antikythera mechanism, probably made by a Rhodian craftsman in 87 BC, lost in a shipwreck north-west of Crete in about 80 BC, and salvaged by sponge-fishers in the year 1900. Its 30-odd gears were conserved in lumps of calcareous accretion, which only in recent years became amenable to analysis, by X-rays and gamma-rays, on which D. J. Price in 1974 could base the definitive interpretation. The mechanism computed the synodic month and the lunar year and

the positions of Sun and Moon on the basis of Meton's (about 430 BC) approximation, in which 19 solar years correspond with 254 sidereal revolutions of the moon, or 235 lunations. As many later geared models, it made use of differential gearing.

Fourteen centuries passed before anything nearly as elaborate was made. The interim is filled by the Arabs with their geared astrolabes, and the Chinese with the waterwheel clock made by Chang Ssu-hsün exactly a millennium ago. Later, this clock was perfected by Su Sung, and lost as a link in the development of technology when the Chinese capital K'ai-feng fell to the Chin Tartars in 1126.

The first mechanical clocks date from the end of the thirteenth century, and the equal hour system gained universal acceptance only a century later. Not surprisingly, the first clocks about which we possess detailed information, those of the fourteenth century of Richard of Wallingford and Giovanni de' Dondi, were astronomical clocks. The positions of the Sun, the Moon and the five planets were displayed on separate dials in the latter clock, which is adequately discussed. Regrettably, the same cannot be said for the discussion of Richard of Wallingford's clock, reconstituted by J. D. North and published in final form in 1976: it is unnecessarily brief and marred by errors of detail. Astronomical clocks have been with us ever since those early examples were made.

Astronomical modelmaking received some powerful impulses from developments in cosmography. In 1543 Copernicus published his *De Revolutionibus*, replacing Ptolemy's geocentric Universe by the much more orderly heliocentric one. In 1609 appeared Kepler's *Astronomia Nova* on the properties of the elliptical planetary orbits, providing a new basis for the “equation of time”, that is, the difference between sundial time and mean solar time, indicated in many astronomical clocks. In the course of time the production of these display clocks diverged increasingly from scientific clockmaking, which aimed at greater accuracy, culminating in Harrison's marine chronometer of 1735.

The trail of astronomical clock making brings us back to the late sixteenth century, to the court of the landgrave William IV of Hesse-Cassel, who employed some masters of the craft, Eberhard Baldewein and Jost Bürgi; then to England in the seventeenth and eighteenth centuries, when Tompion, Mudge and Pinchbeck made clocks catering to the tastes of educated gentlemen of the time. Astronomical clocks of heroic complexity were made in Central Europe: for instance, by

Aurelius a San Daniele and David a San Cajetano at the royal court monastery at Vienna during the second half of the eighteenth century; above all, perhaps, the ‘World Machine’ finished by Ph. M. Hahn in 1791. Schwilgué made the astronomical clock in Strasbourg in 1842, more or less in this tradition. His workshop was the germ of the firm of Ungerer, makers of a most elaborate clock for the cathedral of Messina in 1933.

The line to be drawn between astronomical clocks and other astronomical displays is, of course, vanishingly thin. In France a development occurred of clock-driven armillary spheres, of which Antide Janvier finished an outstanding example in 1801. In England, orreries were mainly developed as aids in adult education by instructors such as James Ferguson (1710–76), who, as “Wheelwright of the Heavens” has a chapter devoted to his life and work. This development on the home-front of astronomy gave rise to transparent demonstrational orreries for large audiences, and, therefore, of maximum size—a development which ultimately led to the projection planetarium.

This work germinated a quarter of a century ago as a modest project to compile a list of extant models of the Solar System. In 1970 its scope expanded so as to include astronomical clocks and biographical notes. The result bears traces of this gestation. It is a somewhat uneven, but readable account of the elements of the early history of astronomy, horology and instrument making for the interested amateur, to whom the geometry of the various models is explained especially well. On the other hand, the historian of science will find this book useful too, because it has retained its original character of a catalogue; none other exists. He will recognise some obvious shortcomings—rather heavy reliance on secondary literature, occasional inaccuracies and the absence of a firm terminus to the references. As stated before, the findings of J. D. North—also referred to as J. and J. G. North—on the clock designed and executed by Richard of Wallingford—also referred to as Robert—are rather inaccurately reproduced. The book by Leopold of 1974 on the Reinhold astronomical table clock is not among the references, nor is Maurice's authoritative book on German geared clocks, although an article by the same author in the September issue of the *Connoisseur* of the same year (1976) is included.

These, however, are only minor flaws in this wide-ranging book, which offers much at a reasonable price. □

New in the Monograph Series

THE SINGLE-STRANDED DNA PHAGES [Monograph No. 8]
Edited by D.T. Denhardt, D. Dressler, D.S. Ray

Presented together for the first time are the complete DNA base sequences of representative members of both the filamentous and isometric phage groups. Replication, transcription, and packaging of viral DNA are discussed in detail, with special emphasis on the way in which sequences in the DNA molecule affect DNA behavior. Protein-DNA interactions and the use of the filamentous phages as cloning vectors are also considered.

THE OPERON [Monograph No. 7]
Edited by J.H. Miller, W.S. Reznikoff

The first comprehensive treatment of operons at the DNA sequence level, this book compares the well-developed lactose system with several other bacterial regulatory systems. It explains the results of the latest genetic, biochemical, and sequence studies and gives a detailed molecular picture of gene regulation. Special emphasis is placed on the DNA sequence analysis of different types of mutations.

Photosynthesis in Relation to Model Systems

edited by **J. Barber**

TOPICS IN PHOTOSYNTHESIS, Vol. 3
1979 xii + 434 pages US\$87.75/Dfl. 180.000
ISBN 0-444-80066-2

Volume 3 in this authoritative series highlights those aspects of the photosynthetic process which may have implications in the development of practical devices for solar energy, capture and storage - and thus constitutes a most important contribution to progress in solving this problem.

Hormones and Cell Regulation, Vol 3

Proceedings of the Third I.N.S.E.R.M. European Symposium on Hormones and Cell Regulation, held at Le Bischoffsheim, Bischoffsheim, France, 4-7th October, 1978. Sponsored by Institut National de la Santé et Délégation Générale à la Recherche Scientifique et Technique

edited by **J. Dumont and J. Nunez**

1979 viii + 226 pages US\$39.00/Dfl. 80.00

Volume 3 in a highly successful series that mirrors advances in all fields of cell regulation, this work will be of great value to investigators from a variety of disciplines wishing to keep abreast of developments in the area.

Carcino-Embryonic Proteins Chemistry, Biology, Clinical Application

edited by **Frank-Günter Lehmann**

The publication of this two volume set marks one of the most significant discoveries of our time - that of the existence of carcino - embryonic proteins - and indeed that has already exercised a considerable influence on research in both the basic and clinical sciences.

Volume I

1979 572 pages US\$114.75/Dfl. 235.00
ISBN 0-444-80095-6

The cooperative effort of invited specialists who have distilled their knowledge into a concise presentation of the present status of research into carcino-embryonic

proteins, this volume offers both integrated and comprehensive coverage of all major developments to date.

Volume 2

1979 948 pages US\$114.75/Dfl. 235.000
ISBN 0-444-80096-4

Proceedings of the 6th Meeting of the International Society for Oncodevelopmental Biology and Medicine held in Marburg, Germany, September 17-21, 1978

This volume provides a unique interdisciplinary forum for research and collaboration on onco-developmental gene expression, that will be essential reading for anyone working in the area.

Special price for two volume set:

US\$209.75/Dfl. 430.000 ISBN 0-444-80097-2

An Introduction to Affinity Chromatography

by **C.R. Lowe**

LABORATORY TECHNIQUES IN BIOCHEMISTRY AND MOLECULAR BIOLOGY, Vol 7, Part II edited by **T.S. Work and R.H. Burdon**

1979 iv + 254 pages US\$29.25/Dfl. 60.00
ISBN 0-7204-4223-0 Paperback

This authoritative work delineates the common principles underlying affinity chromatography and shows how they are applied in practice. Ideal for laboratory workers from a variety of disciplines, the wealth of practical detail and illustrations contained in this volume ensure that it will be taken from the shelves and consulted again and again in practical laboratory use.

COMPREHENSIVE BIOCHEMISTRY, Volumes 33 A and 33 B edited by **M. Florkin and E.H. Stotz**

A History of Biochemistry, Part V

edited by **Marcel Florkin**

These latest additions to Professor Florkin's masterful historical survey, A HISTORY OF BIOCHEMISTRY, offer a fascinating insight into the trials and errors of scientific

endeavour - and represent a worthy addition to the series.

Volume 33A: A History of Biochemistry, Part V. The Unravelling of Biosynthetic Pathways.

1979 xii + 420 pages US\$68.25/Dfl. 140.00
Subscription Price: US\$58.00/Dfl. 119.00
ISBN 0-444-80067-0

Volume 33B: A History of Biochemistry, Part V. The Unravelling of Biosynthetic Pathways (continued)

1979 xii + 323 pages US\$52.75/Dfl. 108.00
Subscription Price: US\$45.00/Dfl. 92.00
ISBN 0-444-80068-9

Reviews in Biochemical Toxicology, Volume I

edited by Ernest Hodgson, John R. Bend and Richard M. Philpot

1979 328 pages US\$32.00/Dfl. 65.00
ISBN 0-444-00317-7

A major new series that provides critical and timely reviews of selected topics in biochemical toxicology, with particular emphasis in the areas of detoxication and intoxication mechanisms and modes of toxic action.

Electrokinetic Separation Methods

edited by P.G. Righetti, C.J. van Oss and J.W. Vanderhoff

1979 x + 476 pages US\$68.25/Dfl. 140.00
ISBN 0-444-80113-8

An up-to-date review by a carefully selected group of international experts of the theories and techniques of major electrokinetic separation methods - promises to become the standard handbook on the subject for many years to come.

Techniques of Autoradiography

by A.W. Rogers

Third Revised and Enlarged Edition

1979 xvi + 416 pages US\$65.00/Dfl. 133.00
ISBN 0-444-80063-8

This third edition of **TECHNIQUES OF AUTORADIOGRAPHY**, now accepted internationally as the standard text in the field, has been substantially revised to cater for the many important advances made in a number of areas, particularly in the photographic process and the analysis of autoradiographic data.

Development of Therapeutic Agents for Sickle Cell Disease

Proceedings of the International Meeting on Development of Therapeutic Agents for Sickle Cell Disease held in Paris, France on the 19th - 21st July 1979

Sponsored by the Institut National de la Santé et de la Recherche Médicale, France and the National Institute of Health, Sickle Cell Disease Branch, U.S.A.

edited by J. Rosa, Y. Beuzard and J. Hercules

INSERM SYMPOSIUM, Number 9

1979 xxii + 262 pages US\$44.00/Dfl. 90.00
ISBN 0-7204-0671-4

A timely review of major developments that brings together the results of expert investigators from a variety of disciplines.

The Cholinergic Synapse

Proceedings of the International Conference on The Cholinergic Synapse held in Linköy, Czechoslovakia on the 15th - 19th May 1978

edited by Stanislav Tuček

co-edited by E.A. Barnard, B. Collier, J.S. Kelly, R.M. Marchbanks, H.P. Rang and A. Silver

PROGRESS IN BRAIN RESEARCH, Volume 49

1979 xx + 510 pages US\$92.75/Dfl. 190.00
ISBN 0-444-80105-7

A worthy addition to this authoritative series that will be of particular interest to research workers in the physiology, ultrastructure, biochemistry, biophysics and pathology of cholinergic synaptic transmission.

Meticulous archaeological surveys

J. E. Wood

Megalithic Remains in Britain and Brittany. By A. Thom and A. S. Thom. Pp. 192. (Clarendon/Oxford University Press: Oxford, 1978.) £8.95.

THE senior author of this book, Alexander Thom, is a mechanical engineer and was Professor of Engineering Science at Oxford University for 16 years until his retirement in 1961. For 35 years or more he has devoted much of his life to the study of the many stone settings which are found in the wilder parts of Britain and in Brittany and date from the late Neolithic and Early Bronze Ages. Thom is not an archaeologist and his research is done, not with the spade, but with the steel tape and the theodolite. He has applied his scientific training to the precise measurement and surveying of these remains. His work was originally published in scientific papers, but at intervals he has collected his results together for publication in book form. *Megalithic Remains in Britain and Brittany* is the third book; the earlier ones, *Megalithic Sites in Britain* and *Megalithic Lunar Observatories*, were published in 1967 and 1971.

The new book was written jointly by Alexander Thom and his son Archibald S. Thom, who has been actively working with his father for many years. About 80% of it is based on a series of papers which were published in *Journal for the History of Astronomy* between 1971 and 1977. Some of the paragraphs and most of the diagrams are indeed identical to those previously published in the *Journal*, but apart from the convenience of having Thom's results in one volume, their work gains in significance when it can be studied as a whole. The book is particularly valuable for giving a comprehensive view of their work on the Carnac megaliths; this is the main topic and accounts for about one third of the text. They describe their surveys of the stone rows, give geometrical interpretations and postulate the existence of two prehistoric lunar observatories. Avebury, Stonehenge and the Ring of Brodgar are also analysed in detail, and there are short notes on several lesser sites. There is also a chapter on the geometry of cup and ring marks.

One's first reaction on reading the book is a feeling of admiration and

awe. The whole of its contents is the original work of one dedicated man and his team of assistants. Only someone who has walked along the stone rows of Carnac and Kermario, and seen the vast numbers of stones, the almost impenetrable thickets of gorse which cover the smaller ones and the clouds of voracious midges in midsummer, can appreciate the enormous amount of hard work and discomfort that underlies the Thoms' detailed plans of the alignments. They have raised the standards of archaeological survey work to a far higher level of accuracy than earlier surveyors of stone rows, and the archaeological community should be ever grateful.

In the course of his studies, Professor Thom arrived at three conclusions: (a) that the non-circular stone rings were not merely accidental departures from circles but were intentionally laid out in other geometrical figures, such as ellipses, flattened circles and egg-shapes; (b) that a precise unit of length, the Megalithic yard of 2.722 feet, was used in setting out the stone rows and circles, over the whole area from Shetland to Carnac and for the whole period of Megalithic buildings; and (c) that the function of many of the stone settings was astronomical, either indicating sightlines for observations of the azimuths of the rising and setting points of the Sun and Moon, or as calculators for predicting lunar eclipses.

Thom's conclusions have been hotly debated by archaeologists for more than a decade, and are not fully accepted at the present time. (Many archaeologists, for example, would accept the idea of a local unit of length, but not the universality of Thom's proposal.) In their book there is barely a hint of the controversy. The starting point is the assumed correctness of the elder Thom's ideas, and sites are individually interpreted in that light. There are no alternative explanations and in the minds of the authors there are no doubts.

Thus, the authors' approach is largely to disregard conventional archaeology, and they do not discuss whether their conclusions are reasonable in the light of current archaeological knowledge. The stone circle at Avebury, for example, is analysed by the Thoms as a compound ring consisting of six circular arcs drawn from six centres which are geometrically related to a 3, 4, 5 Pythagorean triangle. It is the most complicated ring in Great Britain. However, archaeologically there are grounds for believing Avebury is earlier than most rings in the British Isles, that early rings were geometrically simple, and that the more complicated rings are the later ones. The Thoms' interpretation does not fit

Appleton books for the medical student:

BASIC SURGERY: A SYMPTOM-ORIENTED APPROACH Bernard Gardner et al

In 600 pages four distinguished U.S. surgeons prepare the student to evaluate and manage the commonest surgical complaints, as they draw on their own clinical experience in a thoughtful presentation of patho-physiology, treatment, repair and recovery. Future practitioners and specialists will find Basic Surgery a model of coherence.

1979 627pp Pa. £13.70

THE HISTORY AND PHYSICAL EXAMINATION Howard P. Lewis

A practical guidebook for the medical student which makes history-taking and physical examinations easy to comprehend and master. It begins with a systematic procedure for obtaining the patient's history, which is paralleled by a photographically illustrated summary of the physical examination. Designed to help students think clinically and construct a differential diagnosis, Dr. Lewis's concise text will promote improved competence.

1979 160pp Pa £5.80

CUTTING'S HANDBOOK OF PHARMACOLOGY Sixth Edition T. Z. Csaky

In a major revision since the 1972 edition, Cutting's Handbook under its new editorship offers readers a fingertip reference to every important drug in current use. Organised in broad pharmacologic or therapeutic groups, each chemical agent is highlighted for these salient features: history, chemistry, mechanisms, toxicity, dose and use. Structural formulae are given so that molecular similarities can be easily compared.

comfortably into the archaeological framework, and archaeologists are bound to ask if simpler constructions are possible. The robustness of their interpretation, such as the possible range of values for the radii of the arcs, is not discussed.

Another example of their conclusions being in conflict with the archaeology is the supposed distant foresight at Stonehenge, called 'Peter's Mound', which was suggested as an indicator for midsummer sunrise. This looked unlikely archaeologically for several reasons, and indeed was shown by excavation in 1977 to be modern, though this fact does not appear in the book.

These criticisms are not meant to detract from the authors' work, for which I personally have considerable

admiration, but are intended to indicate the nature of the book. It is not a balanced account of megalithic astronomy and geometry, but a compilation of original work, the field reports of a team of meticulous surveyors, to which the serious student of the period will turn and which no specialist in the late Neolithic and Early Bronze Ages can ignore. Some of their interpretations may be proved incorrect in the course of time, but this is not particularly important; *Megalithic Remains in Britain and Brittany*, together with Alexander Thom's two earlier works, will be an invaluable source book for researchers for very many years. □

Star formation

Bart J. Bok

Stellar Formation. By V. C. Reddish. Pp. 287. (Pergamon: Oxford, 1978.) Hardback £15; paperback £7.50.

THIS is an interesting volume and I learned much from reading it with care. At the same time, I express deep regret that it came out in print effectively four years after the writing was finished. It covers adequately and thoughtfully the literature available to the end of 1974 and should therefore have been published by the end of 1975. It does not include the new results reported at IAU Symposium No. 75, which was held at Geneva in September, 1976 (International Astronomical Union Symposium No. 75, *Star Formation*, D. Reidel: Dordrecht, Netherlands, 1977), nor does it include researches that were discussed and analysed at the Tucson Colloquium of January, 1978, papers that are now in print (T. Gehrels, *Protostars and Planets*, University of Arizona Press: Tucson, 1979; *The Moon And The Planets*, 19, No. 2, 1978).

There are several very good chapters in the present volume. Chapter 3 deals in a masterly fashion with the determination of the initial luminosity function and the initial mass function. The three chapters that follow it are a bit on the meagre side, but the concluding chapter of the observational

half of the book gives a well-rounded review of the necessary environment for fostering star building from interstellar clouds. Professor Reddish defends strongly the point of view that star formation results almost exclusively as a by-product of the formation of H_2 molecules on very cold solid particles in interstellar clouds. I agree that this is a major contributing process, but there are regions in the heavens, notably in the Magellanic Clouds, in which cosmic dust particles and even H_2 molecules seem to have played less of a part than neutral atomic hydrogen.

Professor Reddish's independent and honest scholarly considerations have led him to visualise ahead of his time one major process contributing to star formation, but he ignores others. If I were asked to list my favourite processes for star formation, I would list five, which seem to be at work in our galaxy within 1,500 parsecs of the Sun. These are: (1) The formation of OB stars within large dark complexes such as the Ophiuchus Complex, the Taurus Complex, the Greater Orion Complex and the southern Gum Nebula. (2) The Elmegreen-Lada process according to which a large molecular cloud acts as a feedback for the continuous formation of OB stars in the vicinity of established H II regions and associated young OB groupings such as Messier 8 and Messier 17. (3) Supernovae and pulsars, whose high-energy charged particle emissions, along with the Lin-Shu spiral density waves, contribute materially to the condensing of interstellar clouds, thus leading to star formation. (4) Cloud-cloud collisions and interactions between passing clouds, which may further assist condensation

processes. (5) Collapsing large globules (Barnard objects), of low temperature and chockerbloc-full with CO (and thus with molecular hydrogen), provide a good basis for the building of less massive stars; two Herbig-Haro Objects have been found associated with a southern globule (see *Publ. Astron. Soc. Pacific*, October, 1978). Professor Reddish alludes vaguely to most of these processes, which were, however, not generally recognised as being as basically important in 1974-75 as they are today. I wish we might persuade him to add an additional volume to his present offering and bring us up to date.

The second half of the book presents the more theoretical aspects of star formation. It is an excellent and comprehensive treatment but it too is dated. He shows nicely that the physical properties of interstellar gas and dust are such that an interstellar cloud structure is inevitable. Chapter 9 is a most readable presentation of the Lin-Shu density wave theory of spiral formation and its effect on interstellar cloud evolution. There follow very fine chapters on cloud contraction, especially on fragmentation and its effects on the distribution of protostar masses. The chapter on the rate of star formation is regrettably brief and the concluding chapter on the evolution of galaxies did not stir this reviewer.

The book is nicely produced and the medium-priced paperback edition handles well. There are a few places in which a little more care in proof-reading would have been helpful; I noted that the word "asymmetry" is consistently misspelled (pp153, 164, 165). On page 171, there is a reference to (Roberts, 1969); one finds in the bibliography two such references—one to M. S. Roberts, the other to W. W. Roberts—the second one being the one that is indicated.

Because of its underlying unified personal approach of Professor Reddish, this is a book that should be read by everyone who works in the field of star formation. Once one accepts the obvious limitations, we can all learn from his treatment of star formation. This is a good book to assign to one's students, provided it is supplemented by the other volumes mentioned in my review; it is a good treatment for the beginning graduate student, and it should also appeal to advanced undergraduate students in the physical sciences. Professional physicists will find that this book has much to offer, as will informed amateur astronomers. □

Bart J. Bok is Emeritus Professor of Astronomy at the Steward Observatory, University of Arizona, Tucson, Arizona.

Teaching science is our business. Just a few of the new titles in the Earth Sciences from our 1979 publishing programme:

Ancient Environments Second Edition

Leo F. Laporte

A well-balanced study of communities and their environments which examines how to interpret the habits and habitats of fossil organisms. This second edition is expanded to include three new chapters on Taphonomy, Environmental Analysis and Environmental Synthesis.

1979 176pp Cl. £7.25 Pa. £4.35

Economic Geography Second Edition

*John W. Alexander and
Lay J. Gibson*

This major revision of a best seller gives the student access to the principles of economic geography: the theory of the location of economic activity and its application to geographic aspects of major economic activities. The authors build a bridge between traditional classical geography and a new mathematical geography.

1979 496pp £12.35

Fundamentals of Meteorology

Louis J. Battan

This clear, concise introductory text by an internationally recognised authority provides a comprehensive introduction to meteorology and climatology for students with a limited knowledge of mathematics, physics or chemistry.

1979 288pp £10.90

Geochemistry

Arthur H. Brownlow

This new text provides a thorough introduction to the entire field of geochemistry which will be invaluable to professional scientists as well as students. Assuming a basic knowledge of geology, mineralogy, chemistry and calculus, the book combines the latest developments in geochemistry with traditional geochemical principles and applies them to specific geological problems. Theoretical, laboratory, and field studies are incorporated into these problems.

1979 528pp £14.55

Groundwater

R. Allan Freeze

This comprehensive, up-to-date text uses an interdisciplinary approach to groundwater hydrology. It maintains a comfortable, easy writing style, but applies rigorous scientific method for students in geology, civil engineering, agricultural engineering, soil science and geography with a knowledge of introductory geology, physics, chemistry and calculus.

1979 624pp £20.45

The Solar System

John A. Wood

This new text offers a clear introduction to the geology of other planets in the Solar System, the origin and earliest evolution of the planets, and the pre-Solar System history of the chemical elements that comprise the planets. For courses in geochemistry, precambrian geology, space science, the solar system, and planetology at all levels with a prerequisite of elementary chemistry and algebra.

1979 208pp Cl. £8.00 Pa. £5.05

Stellar evolution

R. J. Tayler

Stellar Evolution. Second edition. By A. J. Meadows. Pp. 171. (Pergamon: Oxford, 1978.) Hardback £7.50; paperback £2.50.

THE subject of stellar structure and evolution is believed to be the branch of astrophysics which is best understood. Because most parts of physics—such as nuclear physics, atomic physics, thermodynamics and statistical physics, electromagnetism and gravitation—are involved in determining the structure of a star, it is a very suitable topic in applied physics to introduce to undergraduates. It is also possible to present the subject to an audience with a slighter knowledge of physics and this is the concern of Professor Meadows.

When the first edition of this book was published in 1967, it received a warm welcome because of the manner in which it bridged the gap between very superficial discussions of stellar structure and evolution in books for the layman and complex mathematical texts for the professional astronomer. Twenty years earlier George Gamow's book *The Birth and Death of the Sun* had served a similar purpose, but by 1967 this was seriously out of date in detail. The first edition of Meadows' book gave a clear account of the observed properties of stars and the manner in which they are obtained. It then discussed the principles underlying the structure of stars, the source of the energy radiated from stellar surfaces, the manner in which this energy travels from the centre to the surface of a star, and the physical state of the matter inside stars. The remainder of the book was concerned with the evolution of stars from their birth as dense condensations in interstellar gas clouds, through the major part of their life as main sequence stars (the present state of the Sun) and subsequently as red giants, to their death as white dwarfs, possibly after a supernova explosion. It was then difficult to see how our knowledge of stellar evolution could be treated in a significantly clearer manner without the introduction of mathematical detail, which was completely absent from Meadows' book.

The first edition has now been revised to take account of developments in the subject. Most of the book has been photographically reproduced from the first edition and in most places it is possible to see where changes have been made because of a slight variation in

contrast of the type. In the first half of the book there are only a small number of detailed alterations but later there are much more substantial changes, particularly in chapters 6, 7 and 8. The book is essentially unchanged in length, the addition of new material being balanced by the removal of speculative or unimportant material.

Substantial changes in the new edition include the following. A section has been added on the solar neutrino experiment, the results of which are at present the major question mark against the standard view of stellar structure. There is a completely revised discussion of the evolution of low mass stars following the helium flash, the explosive onset of the conversion of helium into carbon. The major change concerns stellar old age and death. Shortly after the first edition appeared, pulsars were discovered and it was

soon realised that they are neutron stars. It now seems certain that neutron stars rather than white dwarfs are a normal end-product of a supernova explosion. In addition it has been realised that sufficiently massive stellar remnants will be neither white dwarfs nor neutron stars but will be black holes. Rather surprisingly in view of the great current interest in close binary stars and mass exchange between their components, the section on this topic has been slightly reduced in length, although there is a brief mention of the possible detection of a black hole in Cygnus X-1.

The revised edition of this book remains a very good non-mathematical introduction to stellar evolution and the paperback edition is very reasonably priced. □

R. J. Tayler is Professor of Astronomy at the University of Sussex, Brighton, UK.

Microcosm of astrophysics

F. Graham Smith

The Crab Nebula. By Simon Mitton. Pp. 194. (Faber and Faber: London; Scribners: Totowa, New Jersey, 1979.) £6.50; \$14.95.

THE 900th birthday of the Crab Nebula was celebrated by radio astronomers in July 1954. At that time it was almost the only celestial object, apart from the Sun, where a close link between optical and radio astronomy had emerged. In these days, when such links have appeared throughout astronomy, the Crab still has a unique importance, and annual celebrations of the supernova explosion would still be appropriate. Geoffrey Burbridge once said that astronomy could be divided into two parts: the astronomy of the Crab Nebula and the astronomy of everything else. There are indeed links between the Crab and almost everything else in astronomy, so that a discourse on the Crab can be used as an introduction, for example, to astronomy, stellar evolution, cosmology and interstellar matter; including the Crab Pulsar extends the list to the physics of condensed matter, high energy electrodynamics, superconductivity, and many other aspects of quantum physics.

This microcosm of astrophysics can therefore be used as a general introduction to astronomy, which should appeal to any scientist and which may persuade some that astronomy is a very useful means of education in basic physics. Popular books on astronomy

often do not succeed in presenting the more serious aspects of the subject, and their readers might not realise the important part which is played by astronomy in postgraduate physics education. Mitton is a physicist, and emphasises the basic physics throughout, but his book is nevertheless a popular book. He eschews mathematics, and uses not a single equation. The reader need only be moderately numerate, so that he can appreciate the large powers of ten involved in any branch of astrophysics.

The decision to exclude mathematics reduces the astronomy of the Crab to less than half of the total of astronomy; and further choices have been made. Mitton has chosen to make the book readable, straight through, for anyone with an undergraduate level of physics or astronomy. Others, with less expert knowledge, will enjoy at least the historical accounts of the supernova explosion, gleaned from Chinese and Japanese records of the "guest star", and the more recent history of discoveries—notably of the pulsar which remains the centre of the nebula, providing the powerhouse for the energy to keep the nebula shining. For the physicist, the exposition of the basic concepts of degeneracy in white dwarfs and neutron stars, and of superconductivity, will have a strong appeal, as they show most clearly the connection between terrestrial and celestial solid-state physics.

Mitton is an enthusiast. In conveying his enthusiasm he does sometimes overstep the mark, in such purple passages as his description of synchrotron radiation: "photon screeches from very energetic electrons as they wrap themselves round the ambient magnetic field". He refers to the giant pulses from the pulsar as "jumbo", he tells us

that the "youngest pulsars are the jazziest". He also obtrudes a view on space research: the X-ray observations were "made at truly vast public expense". Colourful presentation, but nothing incorrect. Colour is a strong advantage in places—for example, where the energy of one mosquito is given as a million million electron volts.

The astrophysics is sufficiently complete and correct that one can regret quite small omissions, such as the optical polarisation of the pulsar, and

wish to dispute the conclusions on the birthrate of neutron stars in the Galaxy. The serious reader is encouraged to consult a useful but rather short bibliography. This will certainly not be adequate for astrophysicists, and the index is also far too short. Nevertheless, the book is strongly recommended. □

F. Graham Smith is Director of the Royal Greenwich Observatory, and Visiting Professor of Astronomy at the University of Sussex, Brighton, UK.

Anatomy of a stellar murder

Donald D. Clayton

Stars: Their Birth, Life and Death. By I. S. Shklovskii. Pp. 442. (Freeman: San Francisco and London, 1978.) £10.70.

ARE you a practising astrophysicist unable to keep up with the literature, too fatigued by your own specialty? Are you worried that you are becoming too narrow while an exciting flood of astrophysical discovery flows all about you? Then this book is for you. Or are you a physicist wondering what the physics of modern astronomy is all about? This book is for you too. It is also for the amateur astronomer or the student who wants to hear the real issues of astrophysics from one who wrestles with them and who can also describe them without needless complication on the one hand or sterilising simplifications on the other.

Iosif Shklovskii writes incisively about the full range of what I would call stellar astrophysics. Not addressing extragalactic astronomy or cosmology on the one extreme, nor the origin and evolution of the Solar System at the other, Shklovskii concentrates on "stars, the most interesting and important objects in nature." But what stars! Not the serenely twinkling objects we see above us, but rather the collapsing, masering, exploding, bouncing, pulsing, bursting, spinning, extincting labour of birth and violence of death in the heavens. What makes his "serious popular book" (in the author's own words) so exciting is the closeness of many thrilling discoveries to Shklovskii's own career. His brilliance as a thinker and writer is evident throughout, not at all dampened by what must be a very good translation from the Russian, in which language the book was first published in 1975. This English edition has been updated by the author

to render it even more current, although currency is not the main objective.

Perhaps the book should have been called *Anatomy of a Stellar Murder*, so vividly described are the clues marking the birth, ageing, and death throes of its central character. The reader feels like a detective on the case. The book unashamedly emphasises the newer areas of astrophysics, especially the evidence of birth in molecular clouds and the phenomena associated with neutron stars. Shklovskii correctly credits radio astronomy with the leading role in these discoveries, perhaps somewhat under-representing the contemporary excitement in optical astronomy because it is older and, alas, just as taken for granted as a wife of several decades. It would have been Shklovskian to have paused to conjecture how

different it would all have been had we by accident evolved within an optically opaque atmosphere.

This book is quantitative, but not mathematical, displaying only important equations. A strong point is the presence of the many clarifying figures, which seem almost as abundant as the equations. Not designed as a textbook it would nonetheless fascinate final-year astronomy undergraduates or beginning research students, and could be supplemented by physics derivations in class. I would use it for such purposes without hesitation. In fact, the publisher should for this market consider issuing a separate companion paperback of derivations and problems at this level. This is, however, a personal book with the author as its main attraction. It has no references, except a general list at the end, but Shklovskii is liberal with text credits to pioneering researchers. The fact that half of these salutes are to Russians and to himself seems, in this case, justifiable by the author's own major role and by a general lack of awareness in the US of research in Russia.

The book is in four parts, having a total of 24 chapters. Some of the chapters, especially those on Cosmic Masers, Evolution of Protostars, the Crab Nebula, Neutron Stars and Pulsars, and X-ray Stars, are so fascinatingly written as to be pinnacles of astronomical exposition. Don't tell me that when it comes to writing serious popular books there is no difference between a great thinker and merely a great writer. Shklovskii is in the former league with Fred Hoyle and Carl Sagan. Only in the chapters on normal stars does Shklovskii lose the torch. In discussing white dwarves, for example, he seems to slip from his role as excited guide to that of teacher, beginning to wax pedagogical. Stellar structure and evolution suffers also in comparison, results of calculations tending to supplant discussions of physical mechanisms. Nucleosynthesis in stars is not described at all. A few controversial positions are taken up, such as that the admixture of overlying ³He excesses is the resolution of the solar neutrino problem. But maybe it is only in the eyes of this reviewer that this part of the book seems less stimulating than the mystery of the death screams of the heavenly moribund.

All in all, this is a wonderful addition to the astronomical literature, not only as an introduction to modern issues in stellar astrophysics but also as a chronicle of the way of thinking and the temperament of one of its most colourful practitioners. □

Origin of the Solar System

Fred L. Whipple

The Cosmogony of the Solar System. By Fred Hoyle. Pp. 168. (University College Cardiff Press/ Christopher Davies Publishers: Swansea, UK, 1979.) £7.95.

THIS book is not for the general public nor even for the serious amateur astronomer. The physics and the mathematical equations are critical to much of the discussion and, even though painstakingly explained, remain high hurdles for readers without advanced training in these subjects. On the other hand, Sir Fred writes down to research students and to his scientific peers. Had he published the book a decade or so ago as a scientific monograph with proper referencing to the host of contributors to the field, it would have been a useful summary of Sir Fred's imaginative thinking on the subject. It could have stimulated progress in understanding the complex processes that combined to form the Solar System and helped explain how we came into being. Today *The Cosmogony of the Solar System* serves chiefly as an historical document which can be seen to illustrate the formidable intricacy of the problem as measured in masses of data, in diverse physical processes and in time sequences of events.

Nearly everyone agrees on the gross simple picture. Collapse within a black interstellar cloud of dust and gas formed the Sun, the planets, the asteroids and the comets. Since 1950, when the comets were recognised as dirty ice balls, it has been apparent that temperature was the controlling factor in the evolution of the Solar System. The temperature decreased with increasing solar distance. Near the Sun only rocky material could freeze, so that within Jupiter's orbit dust aggregated to form planetesimals and the rocky terrestrial planets. Beyond Saturn icy cometesimals were the building blocks that formed Uranus, Neptune, probably Pluto, and some of the satellites of the great planets. Jupiter and the Sun are considered by some investigators as a double star system and in a certain sense Sir Fred agrees. This all happened 4.6 Myr ago. The details remain obscure and therein lie the controversies. Some of these complications are elaborated in *The Cosmogony of the Solar System*.

Sir Fred makes the basic assumption that the black cloud collapsed to the

radius of Mercury's present orbit, then expanded as a rotating disk star to the limits of the planetary system. His concept fails in at least three major respects, each of which is well documented in the literature and each of which negates most of his thesis. First, a collapsing cloud in the interstellar medium cannot collapse as a simple entity. Nature really does abhor a vacuum; the collapse brought with it an influx of outlying gas and dust, horribly complicating the situation. Secondly, Sir Fred utilises "magnetic brushes" from the rapidly rotating central mass to expand the dust. He assumes that the expanding gas will carry along solid particles that condense as the temperature falls with distance. In fact, the gas in the disk carries an outward radial pressure that reduces the effective central gravity field. The solid particles feel only the gravity field and try to revolve faster than the gas. Thus, the gas acts as a resisting medium causing the particles to spiral inward. No rocky material, therefore, should progress beyond Jupiter's orbit, contrary to the evidence from comets and probably Uranus, Neptune and some outer satellites. Thirdly, Sir Fred adopts the "minimum mass" concept which assumes that the only matter "wasted" from the system is gas that could not condense into the planets, asteroids and comets. The other strongest proponents of the "minimum mass" concept (to whom he does not refer) have long since abandoned the

idea. Also Sir Fred's ingenious removal process—interaction with interstellar clouds—is marginally possible at best. It fails completely if nature is really as wasteful as most investigators now believe.

The accounts of the aggregation of condensates into planets are lucid and Sir Fred presents clearly the problems of explaining rotations. His thinking here follows current conventional patterns except for Jupiter and Saturn. Great uncertainty, however, remains as to the processes which formed these giant planets. Some of the geophysical presentations will surely raise eyebrows and comments among specialists, particularly the concept that radioactive elements such as potassium, uranium and thorium were concentrated in the upper mantle of the Earth as a late time-sequence layering process rather than by magmatic differentiation. Related concepts of lunar evolution and structure are also novel and highly controversial.

As for Sir Fred's proposal that life originated in comets, I am charmed but not impressed by the picture of life forms developing in "warm little ponds," protected in their icy igloos from the cruel cold and near vacuum of open space and falling to primitive Earth at speeds exceeding eleven kilometres per second. □

Fred L. Whipple is Phillips Professor of Astronomy Emeritus at Harvard University, and Director Emeritus of the Smithsonian Astrophysical Observatory, Cambridge, Massachusetts.

Heroes on the climatic stage

W. S. Broecker

Ice Ages: Solving the Mystery. By J. Imbrie and K. Palmer Imbrie. Pp. 224. (Enslow: Short Hills, New Jersey; Macmillan: London, 1979.) \$12.95; £6.95.

ANY hit parade of prominent problems in the Earth sciences would have to include among its top ten the cause of the glaciations which have plagued the Pleistocene. Despite the prominence of this problem relatively little has been written about the history of the endeavour to explain the instability in our planet's climate. The Imbries have not only plucked this plum but have done a superb job. They provide a very readable insight into not only the development of scientific thinking on this subject but also into the person-

alities of the key participants.

It is a book of heroes. Croll, from the Imbries' ancestral Scotland, receives top billing for his role in advancing the orbital theory Milankovitch, with whose name the orbital theory is

James Croll

normally linked, is portrayed as a patient and confident mathematician who devotes his life to calculating the geographical and temporal variations in monthly isolation. John Imbrie's fellow detectives in the current investigation aimed at tracking down evidence in support of the orbital theory are given strong supporting roles.

The Imbries' account shows how personality conflict and serendipity complicate the path towards scientific discovery. Rarely does the key evidence emerge from a carefully planned strategy. More often it emerges from arguments between parties holding divergent views or from measurements made for some other purpose. Perhaps one of the greatest contributions of books like this is to demonstrate to the public the necessity of supporting basic research. The carefully designed pert charts of government agencies rarely produce major discoveries. Creativity cannot be programmed.

The Imbries' account shows the incredible breadth of evidence and technique which have contributed to our understanding of climatic history. The stage is successively dominated by the field geologist observing grooves and erratics, the oceanographer looking

down the microscope at microfossils from deep sea cores, the isotope geochemist with his mass spectrometers and radioactivity detection systems, by the paleomagnetician, and yet again by the field geologist and by the micropaleontologist. Interwoven with field observation are mathematical calculations involving celestial mechanics, isolation dynamics, factor analyses and spectral analyses.

The Imbries are evangelists actively involved in the revival of a once prominent and then much maligned hypothesis. Although they wish the reader to believe that like continental drift the Milankovitch hypothesis is being swept back into fashion by a landslide of new evidence, this reviewer suspects that the CLIMAP *blitzkrieg* will be slowed by a wave of resistance. Like Agassiz, Imbrie and his colleagues will encounter the Bucklands and Lyells of modern meteorology. They are steeped in the dogma that the orbital changes are far too weak to be responsible for the awesome changes from a glacial to an interglacial world. Thus, rather than constituting the final report on solution of a major scientific problem, the Imbries' book will more likely prove to be a status report on a continuing investigation. Many new heroes will likely occupy the climatic stage before the mystery is solved.

The Imbries' enthusiasm for the isolation hypothesis in no way detracts, rather, it gives the book an excitement which allows it to transcend most treatments of the history of science. Their book does for climate what J. D. Watson's *The Double Helix* did for

molecular biology. It allows the reader for a few hours to participate in the intrigues, the mystery, and the excitement of scientific discovery. I heartily recommend this book not only to my fellow Earth scientists but also to their wives, children, neighbours and acquaintances who find it difficult to comprehend our preoccupation with the past. □

Joe Schwartz

Experiencing Science. By Jeremy Bernstein. Pp. 275. (Basic Books: New York; Burnett Books/André Deutsch: London, 1978.) £5.95.

JEREMY BERNSTEIN could be called the C. P. Snow of the 1960s. Writing with an authority and confidence characteristic of Snow's novels Bernstein communicated a literate insiders view of the high energy physics community during the easy money days of ten years ago. The present collection of articles, published from 1969 to 1978 reflects the strains induced in science by the financial stringencies of the seventies and a different social and political cli-

mate. Bernstein begins to show signs of struggling with the changed circumstances, but the results are not as satisfying as his earlier work.

His evaluation of Nora Sayre's book on Rosalind Franklin suffers from an insensitivity to the very real difficulties women experience in a male dominated profession. By concentrating on the facts of the case as presented in Robert Olby's book, *The Path to the Double Helix*, Bernstein chooses to avoid the underlying issues of patriarchy and male domination that prompted Ms Sayre to write her book in the first place. This attitude intervenes to weaken an interesting attempt to describe Bernstein's personal struggle to understand Goedel's Theorem (there exist true mathematical statements that are unprovable). Bernstein introduces a lady friend, K., with whom he will discuss his difficulties. Unfortunately all she does is cook him a meal, listen to a lecture and go to bed. She has no lines of her own. K.

Invertebrate Structure & Function

Second Edition
E J W Barrington FRS

This classic text, providing a comparative treatment of animal structure and function as exemplified by the invertebrates, has now been greatly expanded. It offers a more comprehensive treatment of invertebrate movement, an extensive discussion of chemical communication, which takes account of recent developments in invertebrate endocrinology, and a lengthier analysis of animal associations. Numerous passages have been reworked to take account of new findings and 170 new figures and tables have been added.

ATLAS OF PROTEIN SEQUENCE AND STRUCTURE

Supplement 3
to Volume 5
1978

Margaret O. Dayhoff, Editor

New information on over 365 protein and peptide sequences, 30 RNA sequences, 2 viral genomes, 42 alignments of related sequences, 43 matrices of difference, 15 stereo-pair drawings, 27 evolutionary trees, 47 other figures, 37 tables, superfamily list, cumulative index of protein sequences.

Also Available

PROTEIN SEQUENCE DATA TAPE 78 (for personal use of purchaser only)
M.O. Dayhoff, L.T. Hunt, W.C. Barker, R.M. Schwartz, and M.C. Blomquist
1,081 protein sequences from Vol. 5 and Suppls. 1, 2, and 3.

NUCLEIC ACID DATA TAPE 78 (for personal use of purchaser only)
M.O. Dayhoff, R.M. Schwartz, and B.C. Orcutt
111 RNA and DNA sequences; segment dictionaries from 4 genomes.

PROTEIN SEGMENT DICTIONARY 78
M.O. Dayhoff, L.T. Hunt, W.C. Barker, R.M. Schwartz, and B.C. Orcutt
Key-amino-acid-in-context alphabetized listing of over 121,000 segments, 15 residues in length, from the Protein Sequence Data Tape 78.

The Atlas of Economic Mineral Deposits

C. J. DIXON

Published in USA and Canada
by Cornell University Press.

The *Atlas* illustrates and describes the geological features of a selection of the world's most important mineral deposits. Forty eight deposits are included, which cover the geological types recognised by economic geologists and cover as wide a range of mineral commodities as possible. Although the *Atlas* does not deal with bulk constructional materials or mineral fuels (except uranium), both metallic and the more specialized non-metallic minerals are covered.

Each deposit is presented as a plate of maps and diagrams and is accompanied by a page of notes including background information on the geographical setting, history and mining as well as the geology.

could have been a mathematician and Bernstein the listener which would have given him a chance to show more directly where his understanding breaks down. Instead we end up hearing a lecture rather than seeing the kind of effort it takes to understand the complexities of metamathematics.

But the long piece on US physicist I. I. Rabi is a gem. This is Bernstein at his best. We have a fascinating story of the shift of the centre of gravity of physics research from Europe to the US in the inter-War years as seen through the eyes of Rabi, a Nobel Prizewinner in 1944 for work on molecular beams. Bernstein succeeds in presenting a fresh account of the most romantic period in the history of physics. Here is Rabi criticising the

present division of labour between theorists and experimentalists in physics: "You do an experiment because your own philosophy makes you want to know the result. It's too hard, and life is too short, to spend your life doing something because someone else has said it's important. You must feel the thing yourself—feel that it will change your outlook and your way of life. You must bring it back to the human condition, the human expression—much closer to what the artist is supposed to feel." In the present period there are not many physicists who can experience this kind of emotional commitment to their research. □

Joe Schwartz is on leave from the City University of New York.

Gravitation and the expansion of the Earth

T. C. Van Flandern

Cosmology and Geophysics. By P. S. Wesson. Pp. 240. (Adam Hilger: Bristol, UK, 1978.) £17.50.

It is not immediately evident that the book's two subjects, cosmology and geophysics, have very much to do with each other. The primary connection is through expansion of the Earth, a predicted consequence of several recently proposed cosmological theories and a favourite theme of the author. If the Earth does indeed expand with time, this provides a driving mechanism for continental drift, a simple understanding of how the Earth's surface became partitioned into continents and ocean basins, and in general a deeper understanding of the origin and evolution of the surface features of planetary bodies. The evidence that the Earth has, in fact, been expanding in the past is still debated; but the author presents a credible case for his interpretation. The evidence ranges from the suggestion that all of the continents would fit together nicely on a globe having one-fourth the Earth's present surface area, to palaeomagnetic determinations of the Permian radius, and arguments from logic: How could Antarctica become almost surrounded by an ocean ridge, with which it was once supposedly in contact, unless the globe has expanded?

Two mechanisms for producing the

expansion are offered, and this leads us immediately into cosmology. The first is that the universal gravitational constant may be decreasing; the second is an expansion of all macroscopic bodies and the space they occupy relative to the size of the atomic particles which comprise them, at the same rate as the observed large scale expansion of the Universe. These two mechanisms can now be unified into a single theory, which has been the direction that most theoretical work has taken since this book was written.

The book opens with an excellent survey of variable-*G* cosmologies and what motivated them; Milne, Dirac, Jordan, Gilbert, Brans and Dicke, and Hoyle and Narlikar are all reviewed. There follows a general discussion of post-Einstein gravitational theories, of the various attempts to incorporate Mach's Principle of Inertia into these theories, of space variability of the gravitational constant, vacuum elasticity, possible anisotropy of gravitation and the limits placed by the Eötvös experiment, and additional related topics. There is then an entire chapter devoted to the Eddington numbers, which form the basis of the Large Numbers Hypothesis and the motivation for the original 1937 proposal of Dirac that gravitation must be weakening with time. This chapter also discusses experimental limits on the variations of other fundamental quantities, such as the fine structure constant, and discusses the physical and astrophysical consequences of the proposed changes in fundamental constants of physics.

This summarises the first half of the book. It is a truly excellent review with a very complete bibliography. Moreover I was pleased to see explicit mention of the assumption underlying this entire discussion, that there may be as yet undiscovered laws of physics. This

has always seemed to me an obvious point as long as our understanding of the true nature of phenomena such as gravitation is so limited (Why do masses attract only? Is there a quantum of gravitation? Is shielding possible?); yet it is an assumption few physicists seem to make. The only criticism to this point is that reading would not be easy going for the novice, as specialised terms are sometimes introduced with only very sketchy definitions and no real attempt to provide understanding of the concepts. There is also confusion on p42 about just what information ancient eclipses provide.

The second half of the book deals with experimental evidence on changes in gravitation and Earth expansion, and an attempted reconciliation of such concepts with Relativity Theory. The author very much favours the idea that the Earth has nearly doubled its radius in its lifetime, rather than the more modest expansion of perhaps 10% allowed by a weakening of gravity. I think he has overlooked a valuable argument. We know that the Moon must have been quite close to the Earth in the past; the best estimates place the closest approach at about 3×10^8 yr ago. Tidal friction under these circumstances must have been enormous, and surely must have produced considerable internal heating and expansion of the Earth. Moreover, if the Earth had a much smaller radius than at present for most of this early period, this would help explain why the tidal coupling coefficient has averaged less than half its present value since the Moon was close. Whether the expansion continues today would then depend on whether gravitation is weakening; but the bulk of the expansion would have taken place early in the Earth's history. Moreover, it is important to keep in mind that expansion from any cause would surely occur in discrete events rather than continuously, as radial strain, like horizontal strain, would have to reach a threshold before the Earth would yield. It is interesting to note the recent discovery of a huge surface fissure on Venus, comparable to the largest known on Mars. Taken with the large Van de Graff lunar farside surface depression, it is probably not premature to infer that expansion may indeed be a regular feature of planetary evolution. If so, Wesson deserves much of the credit for advocating the idea while it was still unpopular, and for placing it in a reasonable theoretical and observational perspective. □

Key to the mysteries

John M. Charap

Einstein's Universe. By N. Calder. Pp.147. (Viking: New York; BBC Publications: London, 1979.) \$10; £6.25.

SOME of the very best popularisations of science to have been published in the past decade have had their origin in BBC television productions: these have included Nigel Calder's own *Violent Universe* and *The Key to the Universe*. And now comes, in celebration of the centenary of Albert Einstein, *Einstein's Universe*. As in his earlier books, Mr Calder has drawn upon the resources deployed by the BBC in their original telecast form and has made a brave effort to meet the challenge inherent in explaining the intellectual achievements of fundamental physics without either scandalising the experts, boring the lay readers for whom he writes, or still worse misleading them. That there is a very significant desire for information, a craving for a simple route to understanding, a key to the mysteries, cannot be doubted. Any physicist who has been button-holed at a cocktail party and asked to 'explain' quasars or lasers, quarks or black holes, can testify to that. But he can also give evidence of the difficulties: how to explain modern physics to an intelligent, inquisitive but non-numerate questioner whose understanding of classical physics is likely to be non-existent. It's not just making the progression from nineteenth-century science to quantum physics and relativity, but rather going from Aristotle to Einstein leapfrogging Newton.

The millions who watched the television broadcasts may have been satisfactorily distracted by the glamour of the hardware, or entertained by Peter Ustinov's German accent, or fascinated by the contrasting personalities of the contributing scientists. And in his earlier book Mr Calder allowed himself some glamorous packaging, beautiful colour photographs, coffee-table format. This time his approach is more austere: indeed he seems to have taken his task to "make relativity plain" almost literally and *Einstein's Universe* has few illustrations, none in colour. I would even question whether the photographs chosen actually illustrate anything very significant to the purpose of the book, but am grateful for two of Einstein

himself, neither of them over-familiar. Einstein thought visually, as do many creative scientists, and the book would have been better, and the author's task easier, if there had been more and better diagrams. One of the few which actually relate directly to the text (p47) is annoyingly wrong, and even if it were corrected it would still be less informative than might have been possible with better draftsmanship and captioning.

The sequence of topics chosen by Mr Calder to lead the reader right up to today's research is unusual and I think effective. Instead of the conventional historical approach, from special relativity to general, the order is reversed. Moving swiftly from the transverse Doppler effect to $E=mc^2$ and then to gravitation, the basic

Einstein in 1916

Radio Times Picture Library

themes are blocked in. At the same time opportunity is taken whenever it is presented to make reference to the most recent experimental or observational confirmation of the consequences of the ideas. So it is that very early in the book the evidence from astronomy for the existence of black holes, as collapsed stars (Cygnus X-1) or as galactic nuclei (M 87) is woven into the argument. Einstein's contributions in fields other than relativity are also brought in to further the main development of ideas. So his notion of stimulated emission leads through atomic clocks to the gravitational effect on clocks and on time. The 'time-shells', successive zones in which clocks run at greater rates as one goes further from a massive object are skilfully introduced and lead without strain to the gravitational red-shift.

The equivalence principle, so central

to Einstein's own way of thinking is ably introduced in a chapter on weightlessness: the advantage an author who can draw on the reader's experience, if only vicarious, of free-fall in a space-capsule is very substantial and is well-exploited.

The effect of gravity on time is then used as a bridge to the effect of gravity on space. The over-worked, and to my mind misleading analogy with the distortion of a rubber sheet by heavy objects is used, but more telling is the difference in surface area of a sphere enclosing a mass from the $4\pi r^2$ of Euclidean geometry—the surface of the Sun has a 'missing' area roughly the area of the USA.

The famous classic tests of general relativity, and their modern counterparts are all described; not just the perihelion advance of Mercury, but the periastron advance of the binary Pulsar 1913+16. The book went to press when it was only possible to speculate that that same binary pulsar might give evidence through Joseph Taylor's careful and continuing observations for gravitational radiation; that confirmation was announced last December. The deflection of star-light by the Sun observed by Eddington's 1919 expedition is explained, and the counterpart annual observation of the same effect on 3C 279 also described. The so-called 'fourth classic test', the radar echo delay, is here too.

I think the treatment of the observational consequences of general relativity and the present status of such observations, is very good indeed. I'm less happy, however, with the discussion of special relativity, which is often made less than clear by the author's attempts to verbalise the mathematics. However, the reasoning for the apparent rotation of a fast-moving object (and hence its foreshortening) is really very well handled, and overall I think it fair to say that many much fuller accounts of special relativity, in popular or technical treatments, succeed far less ably in getting the basic points across.

The book's last main theme is an exploration of relativistic cosmology; inevitably and quite properly this leads into more speculative areas. In the course of the book we have already had our attention directed to quantum effects, to Hawking's quantum radiation of black holes, to gravitons (there's one sentence I shall try to remember for its explanation of the non-linear effects of quantum gravity: "This incest among the gravitons produces the curvature of space"). And now we meet supergravity and gravitinos, twistors and foamy space.

I enjoyed reading the book. I was occasionally irritated by infelicities like "At its birth light accelerates infinitely

Oxford Books this Spring

Scientific Models and Man

The Herbert Spencer Lectures, 1976

Edited by Henry Harris

A group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe in which we live. Contemporary intellectual revolutions take time to make their full influence felt: this book gives some indication of the way the world is going to look tomorrow. Illustrated £3.25 June

Applied Semigroups and Evolution Equations

A. Belleni-Morante

This book introduces the theory of linear semigroups and of linear, semilinear, and quasilinear evolution equations with particular emphasis on applications. It is intended as an introductory course for final-year undergraduate and graduate students, as well as for physicists and applied mathematicians who wish to see how an abstract theory can be used in connection with concrete problems. £9.75 *Oxford Mathematical Monographs* May

Collected Papers of G. H. Hardy

Volume VII

Edited by I. W. Busbridge and R. A. Rankin

This final volume in the series, the aim of which is to render more accessible the papers of the great mathematician, covers Fourier transforms, integral equations, miscellaneous papers including papers on set theory, differential equations, and the Hardy-Weinberg law, questions from the *Educational Times*, and obituary notices and reviews by Hardy. £30

Chemistry of the Metal-Gas Interface

M. W. Roberts and C. S. McKee

Surface chemistry has been revolutionized by recent advances in experimental techniques such as electron spectroscopy and low-energy electron diffraction. This book presents an account of these developments with emphasis on the basic appreciation of the experimental methods and also on the application of these techniques. £26 *Monographs on the Physics and Chemistry of Materials*

Thermodynamics and Statistical Mechanics

P. T. Landsberg

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way, with the Carathéodory method fully but simply used, without advanced mathematics. The modernization of the whole subject is reflected by the wide range of applications covered, and there is a large number of problems, with solutions. Illustrated £8.50 June

Electronic Processes in Non-Crystalline Materials

Sir Nevill Mott and E. A. Davis

Since the first edition of this highly successful book there has been great development both in the experimental and theoretical studies of the electrical properties of non-crystalline solids, so that it has been necessary to rewrite almost the whole book. The aims of the new edition remain the same, however: to set out the theoretical concepts, to test them by comparison with experiment for a wide variety of phenomena, and to apply them to non-crystalline materials. Second edition Illustrated £22 *International Series of Monographs on Physics* June

Theoretical Cosmology

A. K. Raychaudhuri

Observational and theoretical cosmology are reviewed in this book, with liberal reference to original literature. To a physicist who is not a cosmologist, the book will be a short and accurate review, while to the researcher in cosmology it will be useful for reference and also help to put his work in proper perspective. £10 *Oxford Studies in Physics* May

Disorder in Crystals

N. G. Parsonage and L. A. K. Staveley

This book surveys present knowledge of positional disorder, orientational disorder, and magnetic disorder in stoichiometric crystals, and therefore deals with the nature and interpretation of order-disorder transitions. The relevant thermodynamics and statistical mechanics are discussed, and experimental methods for studying disorder are reviewed. The classes of compounds surveyed include alloys, salts, ice and hydrates, molecular solids, clathrates, and compounds of magnetic interest. Illustrated £28 *International Series of Monographs on Chemistry* May

Oxford University Press

Announcing Volumes 33A and 33B in Professor Florkin's masterful historical survey, A HISTORY OF BIOCHEMISTRY - a fascinating insight into the trials and errors of scientific endeavour - and a worthy addition to the series:

Comprehensive Biochemistry

edited by MARCEL FLORKIN, *Emeritus Professor of Biochemistry, University of Liège, and*
ELMER H. STOTZ, *Professor of Biochemistry, University of Rochester, School of Medicine and*
Dentistry, Rochester, NY, U.S.A.

Part V in Professor Florkin's history, tracing the long process of evolution of Biochemistry, is devoted to the unravelling of Biosynthetic Pathways. and appears in two volumes.

"His (the author's) breadth of coverage and command of scientific detail remind one of Partington's monumental History of Chemistry. When the last part of the history appears the reader will have a very comprehensive account of the history of biochemistry that will also guide him or her to recent work by historians on the history of physiology and biochemistry." **Science.**

rapidly" or "Even more fundamental than the speed of light is energy". (What exactly can that mean?). More serious a criticism is the worry that in spite of his best efforts the reader may fail to grasp the logic of the theory rather than be convinced by evidence in its favour. But Mr Calder has made

a valuable contribution to the demystification of relativity, and one which is most worthy to appear in this year of Einstein's centenary. □

John Charap is Professor of Theoretical Physics at Queen Mary College, University of London, UK.

Einstein's charisma

W. B. Bonnor

Einstein: A Centenary Volume. Edited by A. P. French. Pp. 332. (Heinemann: London; Harvard University Press: Cambridge, Massachusetts, 1979.) £10.50; \$25.

THE personality of an intellectual giant like Einstein exerts special fascination. How far is his genius apparent in everyday behaviour? Does he have special insight into non-scientific matters? How does he get on with his ordinary fellows? It is fortunate from this point of view that Einstein's life and opinions have been so well documented: indeed so much has been written about him that it is quite hard to say anything new.

Einstein: A Centenary Volume was written at the instigation of the International Commission on Physics Education, bearing especially in mind teachers and students of physics at secondary and undergraduate levels. It consists of four parts. Part I contains 18 reminiscences and reflections on Einstein, half of them reprinted from elsewhere. Part II is the main part of the book containing thirteen articles on Einstein's scientific work and political and social ideas. Twelve of these seem to be new, and specially commissioned for the book. Part III contains a number of letters from and to Einstein: it is not made clear which (if any) of these are being published for the first time. In Part IV a number of Einstein's writings are reprinted and a pitifully inadequate bibliography is given. The book contains many interesting photographs and drawings and is lavishly produced. However, it certainly does not offer a rounded account of Einstein's work or his personality, and the statement on the dust-cover that the book is "a total assessment of the life and works of one of the intellectual giants of our age" is unjustified. To mention one important omission, there is no description of

Einstein's work on cosmology.

In the commissioned essays there are several worthy of serious attention. Silvio Bergia gives a scholarly history of the discovery of special relativity, starting from the relativity of Newtonian physics. His article contains a careful judgement of the parts played in the discovery by Lorentz, Poincaré and Einstein, with special reference to the assessment of E. T. Whittaker, who called special relativity "the theory of Poincaré and Lorentz". Bergia concludes that Whittaker's view cannot be sustained, and that the credit usually given to Einstein is justified. There are competent accounts of Einstein and the quantum theory by Martin J. Klein, and of the observational verification of general relativity by A. P. French.

The highlight of the book for me was the article, "Relativity theory and gravitation", by Hermann Bondi. Bondi presents a derivation of general relativity which differs from that of Einstein, and which he attributes to Fock. He starts with the notion of gravitation as a tidal force only, so that a uniform gravitational field is a zero gravitational field; and he discusses the nature of mass, describing the three different sorts and commenting on the non-existence of negative mass (of the reason for which relativity gives no clue). A somewhat

sophisticated treatment of Newtonian gravitation theory is set up for later generalisation. Gravitation is introduced into special relativity by a thought-experiment using the gravitational red shift. A simple introduction to non-euclidean geometry leads painlessly to the Riemann tensor and the equation of geodesic deviation, which is neatly tied up with the Newtonian treatment and the tidal approach. It is beautifully done and should be read by all those interested in general relativity. One feels that Einstein, with his eagerness to explain relativity to the man in the street, would have enjoyed this article.

Among the essays on social and political matters are "Einstein and world affairs" by A. P. French and "Einstein and Zionism" by Gerald E. Tauber. Here Einstein emerges as the idealist, working to put the world right, but almost as much at sea as the rest of us. He espouses utopian ideas such as world government, disarmament and democratic communism; he writes to Roosevelt in 1939 calling attention to the possibility of building an atomic bomb, but later he is horrified when one is dropped; he writes to the President of the USSR Academy of Sciences asking for contributions to a book *One World or None*, and gets a dusty answer. All this was well meant, of course, but how naive and ineffective compared with the majesty of his achievements in physics!

In this field there emerges too a side to Einstein somewhat at variance with the saintliness which his reputation usually enjoys. Although he wrote that he passionately hated "all the loathsome nonsense that goes by the name of patriotism", yet, unable to detach himself emotionally from his Jewish origin, he became a Zionist. He went on fund-raising tours and let himself "be exhibited like a prize ox". Even before the Nazi era, Einstein disliked the Germans and after World War II he developed a pathological hatred of them, calling them mass-murderers. This attitude contrasts ill with that of his Jewish colleague Max Born who showed a gentle forgiveness for Germany after World War II.

Although, as we ought to expect, Einstein had his weaknesses, the book brings out many of his fine qualities. One is his modesty and unpretentiousness—illustrated by the story of how, at a dinner in his honour at which a too fulsome speech was being made about him, he whispered to his neighbour, referring to himself, "But he doesn't wear any socks!". □

Special relativity

Bernard F. Schutz

Special Relativity: The Foundation of Macroscopic Physics. By W. G. Dixon. Pp. 261. (Cambridge University Press: Cambridge and London, 1978.) £14.50.

DON'T let the title deceive you: this is not another introduction to special relativity. This is a book for those of us, working physicists or advanced students, who know a few things about relativity, thermodynamics, and electrodynamics but have not bothered to examine too closely how all these things fit together and on what sorts of assumptions they are based. Graham Dixon's aim is to isolate these assumptions and to derive from them the macroscopic laws we know so well, making full use of the spacetime viewpoint. On the whole he succeeds very well, and the book should prove rewarding to the careful and patient reader.

The first chapter studies the foundations of relativity (special and Galilean). Dixon discards the usual postulates of relativity (that the laws of physics are the same in all frames) and of the invariance of the speed of light (or for Galilean relativity, the usual velocity-addition law) in favour of two other postulates. One is the Principle of Uniformity, that in a given frame, space and time are homogeneous and space is isotropic. The other is the Extended Principle of Inertia, which not only extends the usual principle of uniform motion in the absence of forces to macroscopic bodies but also postulates that a clock's rate may depend on its speed but not on its position or direction of motion. From these two principles and a careful discussion of the nature of measurements, Dixon arrives essentially at the conclusion that the transformation law between the preferred reference frames picked out by the principles must be linear and must preserve the line element $(\delta x)^2 + (\delta y)^2 + (\delta z)^2 - C(\delta t)^2$, for some constant C . The case $C > 0$ is special relativity, and $C < 0$ is excluded by a rather weak argument which would have been unconvincing before the days of particle accelerators. The limiting case, $|C| \rightarrow \infty$, is actually treated separately and is, of course, Newtonian theory. (The case $C=0$ is not discussed but is in fact easy to exclude.) Later Dixon remarks that it seems as if we have got something—a fundamental constant with the dimensions of velocity—from postulates

which seem to have no scale, and that this velocity may originate in the fundamental velocity $\hbar/e^2$ by way of quantum-mechanical nature of the measuring rods one uses. Although there may be something in this, a more direct explanation seems to me to be that his postulates already imply the consistency of using universal units for time and distance, and the only question is what value C has in these units. As the postulates do not restrict C , they do not themselves give a universal velocity. This restriction comes from outside the postulates, by adding that the cases $C < 0$, $C=0$, and $|C|=\infty$ are contrary to experiment. But this is a minor quarrel, which should not obscure the fact that this chapter makes the useful point that special relativity and Newtonian physics need not be derived from such disparate postulates as one usually finds in elementary treatments.

This unity of treatment of relativistic and Newtonian theories is developed further in chapter 2 and then carried through the whole book. Chapter 2 begins by developing affine tensor calculus. The point of view is algebraic rather than geometric, with tensors defined by their transformation properties rather than as linear functions of vectors. Integration on arbitrary surfaces in an affine space E_n is discussed, with a full and clear treatment of antisymmetric tensors, volume elements, orientation and Stokes' theorem. Lie derivatives don't appear here but are introduced very briefly in chapter 4. In order to treat relativity and Newtonian theory in a unified manner, their respective spacetimes are discussed and fundamental tensors defined: the metric for relativity and both a 3-metric and the universal time co-vector in Newtonian theory. (Throughout the book Dixon uses 'Newtonian' to mean a gravity-free spacetime, which others often call Galilean.) A particularly nice feature is a demonstration of how to contract the Lorentz group to get the Galilean group.

There follows a discussion of particle and continuum dynamics, conservation laws, and an especially clear discussion of the effects of forces on mass and energy in both theories. One can also find here in chapter 3 a careful treatment of the 'Newtonian limit', which deserves a careful treatment where mass and energy are concerned.

In chapter 4, Dixon picks up his assertion that the laws of physics are seen most simply from a relativistic point of view by showing how much of thermodynamics and phenomenological hydrodynamics can be derived from exceedingly simple assumptions. His starting point is the entropy-flux four-vector s^μ , which by the second law of

thermodynamics satisfies $s^\mu_{;\mu} \geq 0$, the equality obtaining in equilibrium (but not only there). He defines a simple fluid as one in which s^μ is a function only of the stress-energy tensor and the particle-flux vector, at least in and near equilibrium. From this starting point and using Lorentz invariance he shows that, in equilibrium, s^μ is parallel to the flux vector and the stress-energy tensor is $\text{diag}(\mu, p, p, p)$ in the reference frame defined by s^μ . Near equilibrium the usual phenomenological laws governing heat conduction, bulk viscosity, and shear viscosity come out as first-order corrections, whereas second-order corrections give the time-derivatives in the diffusion laws which are necessary to limit the diffusion to speeds less than that of light. The treatment of the second-order terms seems to follow that of W. Israel (*Ann. Phys. New York*, **100**, 310–31, 1976) to which Dixon refers, but Israel's "cross-coupling coefficients" don't appear here and it is unfortunate that Dixon does not comment on this. It is also sad that Dixon does not refer earlier in this chapter to the often-overlooked work of van Dantzig in the 1930s, who seems first to have introduced "thermasy" ($T\tau$, where τ is proper time), a variable often used by Dixon as a parameter along the world lines of his fluid.

The final chapter gives, for fluids which interact with electromagnetic fields, a treatment largely parallel to the one above, except that here of course there is no point taking any Newtonian limits. It contains a good discussion of the Abraham and Minkowski stress-energy tensors in view of the arbitrariness of any separation between 'fluid' and 'field' for a polarisable fluid. The second-order terms now include other phenomenological terms associated with the Debye and Langevin effects.

Throughout the book Dixon maintains a clear and methodical style. The book is well-produced and admirably free of misprints, the worst of which I found was a statement (p87) that no timelike vector can be expressed as a linear combination of spacelike vectors, in which it is clear from the context that "orthogonal" is intended before "spacelike". It assumes a fair degree of sophistication of the reader, and I would not send a student to it who did not already know special relativity and relativistic thermodynamics from other sources. But I would recommend it strongly for libraries and for anyone who wants to bring a little more order to that jumbled mixture of theory and phenomenology that most of us carry around in our brains. □

A new approach in tissue culture

PETRIPERM

a novel culture dish
with gas permeable
membrane as cellular
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Foundations of Molecular Pharmacology

J. B. STENLAKE

Volume 1: Medicinal and Pharmaceutical Chemistry

This text has emerged from 30 years of teaching undergraduate courses and conducting research in medicinal and pharmaceutical chemistry. It is conceived essentially as a foundation course in the basic principles of organic chemistry applied to the study of medicinal agents and the formulations in which they are used. Intended primarily for undergraduate students of pharmacy and medicinal chemistry up to Honours level, it emphasises the close similarity between chemical and biochemical transformations. This approach should help to give students and others engaged in the design of new drugs a better understanding of the fundamental mechanisms which control interactions between drugs and body chemistry.

Contents: Introduction; The Making and Breaking of Bonds; Alkanes (Paraffinic Hydrocarbons); Alkenes (Olefines); Benzenoid Aromatic Hydrocarbons; Alkynes; Monohydric Alcohols; Phenols; Halogenated Hydrocarbons and Esters of Inorganic Acids; Aldehydes and Ketones; Monocarboxylic Acids and Esters; Dibasic Acids; Oxo- and Hydroxy-Carboxylic Acids; Organo-Sulphur Compounds; Nitro Compounds; Amines and Quaternary Ammonium Salts; Carbamic Acid Derivatives; Amino Acids; Peptides and Proteins; Glycols and Polyols; Carbohydrates; Fused-Ring Hydrocarbons; Hetero-cyclic Compounds; References; Index.

xii, 936 pages, 43 diagrams, 79 tables £36.00

Volume 2: The Chemical Basis of Drug Action

Volume 2 adopts a more broadly based approach and develops the study of some of the more general chemical factors which determine drug action. It is intended for specialists in medicinal chemistry and pharmacy, whether undergraduate, postgraduate or practising medicinal chemists, and should appeal also to clinical pharmacologists and all those interested more in the action and use of drugs than in their design.

Contents: The Characteristics of Drug—Receptor Interaction; Bonding and Biological Activity; Stereochemical Factors in Biological Action; Drug Ingestion, Transport and Excretion; Drug Metabolism; References; Index.

x, 318 pages, 49 diagrams, 42 tables £18.50

MIX AND SPIN PERCOLL™

 **DENSITY
MARKER
BEADS**
NOW AVAILABLE
for calibration of gradients of Percoll

Now centrifugation is simpler,
quicker and gives much greater resolution
than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

THE GREATEST REVOLUTION SINCE THE CENTRIFUGE

Contact your normal supplier today for a free descriptive booklet.

NEW FROM MILES RESEARCH PRODUCTS

REAGENTS FOR IMMUNOHISTOCHEMICAL TECHNIQUES

The constant search for the visualization of specific antigenic substances in cells and tissues has resulted in the development of a number of techniques to accomplish this task. Miles Research Products now supplements our already extensive line of reagents for immunohistochemical techniques with the following products:

FLUORESCCEIN CONJUGATED ANTISERA

Liquid Antisera To:	Produced In:	Code No.
Bovine IgG ₁ (Specific To Subclass)	Rabbit	64-177
Bovine IgG ₂ (Specific To Subclass)	Rabbit	64-178

review article

Dilepton production in hadronic collisions

L. M. Lederman

Columbia University and Fermi National Laboratory, Batavia, Illinois 60510

Quarks play a central part in particle physics. They were introduced as three fundamental, irreducible building blocks whose combinations reproduced the vast spectroscopy and static properties of hadronic states. Here we are concerned with the extension of the quark concept to collisions: the quark-parton model provides a description of the weak, electromagnetic and strong scattering processes.

A GAUGE invariant quantum field theory of quarks and gluons, quantum chromodynamics (QCD) aspires to the fundamental theory of hadron dynamics. This theory, coopting the successes of the quark-parton model, should account for the quark-quark forces which lead to structure functions (momentum space wave functions) of the bound quarks, including the properties of the 'hydrogen-atoms' of quark-quark forces: the $\bar{q}q$ states of massive quarks. Examples of these systems are the recently discovered particles J/ψ and ψ . We also want this theory to explain 'confinement', why quarks are apparently permanently imprisoned in hadrons.

The field has been enriched by the necessity to postulate an increasing number of quarks. The original three have now been joined by a fourth (charm, 1974) and a fifth (beauty, 1977). I consider here one experimental approach which has been particularly fruitful on two fronts: (1) the enrichment in the number of quarks and (2) on sensitive determinations of the properties of the old quarks which are the main constituents of protons and neutrons.

Dilepton production

There has been much theoretical and experimental concern about the high energy collisions of protons with nuclei in which two leptons appear in the final state:

$$p + N \rightarrow \mu^+ + \mu^- + \text{anything else} \quad (1)$$

(In some experiments the muons are replaced by electrons.) The emerging leptons are the only particles observed in these experiments; their momenta and angles are measured and the 'effective mass' of the pair is calculated:

$$m^2 = 2p^+ p^- (1 - \cos [\theta_+ + \theta_-]) \quad (2)$$

As the quantum numbers of the lepton pair are those of a photon, a compilation of the spectrum of effective masses is equivalent to an observation of the (virtual) photon flux generated in high energy collisions.

The effective mass of the muon pair, (that is, the mass of the parent photon) acts as a probe of small distance structure of the colliding hadrons—and the Heisenberg Uncertainty Principle teaches us that the higher the mass, the smaller the detail probed. This was the motivation for the first such experiment carried at the Brookhaven 30 GeV accelerator in 1968¹.

Muons are extremely penetrating, so we can use very intense incident proton beams and protect the detection equipment by thick filters through which only the muons penetrate. Thus one

can select reaction (1) out of processes which are millions of times more probable, and follow the reaction out to large effective masses where the probability of emission is extremely small.

The intuitive idea of probing for small distance structure was quantified by the quark model.

The dynamical property of quarks (the quark picture of high energy collisions) came of age in the Feynman² (partons) and Bjorken³ models in the late 1960s. The first success was the explanation of scaling observed (or so it seemed) in deeply inelastic electron-nucleon scattering. In these models, the hadron is treated as a bound state of elementary, point-like objects, called partons. In the interaction with virtual photons and with the (weak) intermediate bosons, the partons behave as if they are 'almost free'. These ideas are applied to the following reactions:

$$l + N \rightarrow l + \text{anything} \quad (3)$$

$$l + l \rightarrow \text{anything} \quad (4)$$

$$p + N \rightarrow l^+ + l^- + \text{anything} \quad (5)$$

where l can be an electron, muon or a neutrino. 'Anything' is an integration over all possible final states. Reaction (3), already referred to as deeply inelastic scattering has been extensively examined experimentally, beginning with pioneering experiments at SLAC and progressing to much higher energies at Fermilab where the electrons are replaced by muons. In the constituent model, the charged lepton interacts with the quark constituent through the emission and absorption of a photon (virtual) of momentum Q . In this view equation (3) can be written

$$l^+ + q \rightarrow l^- + q \quad (6)$$

The experimental result that most significantly advanced the quark model was the confirmation of Bjorken's prediction of scaling. Scaling describes a particularly simple behaviour of the scattering in which only a particular combination of supposedly independent variables are adequate to describe the data: the combination is written as

$$x \equiv \frac{2m_p \nu}{Q^2}$$

Fig. 1 Data obtained at BNL in 1968 (See ref. 1).

where ν is the lepton's energy loss in the scattering and Q is the momentum transferred, so that the scattering is described by functions:

$$F(x \text{ only}) \quad (7)$$

The scaling behaviour will be shown later to be only approximately true.

Reaction (4) is investigated in electron-positron storage rings. These included facilities at Orsay (France), Frascati (Italy), Novosibirsk (USSR) and, most notably at SLAC's SPEAR and DESY's DORIS. The quark view of equation (4) is:

$$e^+ + e^- \rightarrow q + \bar{q} \quad (8)$$

Given these interpretations, Drell and Yan⁴ interpreted reaction (5) as:

$$q + \bar{q} \rightarrow e^+ + e^- \quad (9)$$

the hard collision of two hadrons to produce a massive lepton pair is viewed as the annihilation of a quark in one with an anti-quark in the other. At first sight it would appear that equations (8) and (9) are simply reversed forms of the same reaction. However, in practice, they teach us quite different things. Quarks do not emerge from collisions but somehow fragment into normal hadrons such as pions, and kaons. Thus reaction (8) informs us about the fragmenting process. Reaction (9) is dominated by the density and motions of the quark and

anti-quark content of the colliding particles and so informs us about the quark structure of hadrons. This would then be the main thrust of dilepton physics except that from time to time, the continuum distribution of muon pairs is interrupted by the resonant production of a massive particle which decays into lepton pairs. This distorted the original Brookhaven spectra¹ but was not perceived because of the poor mass resolution which smeared the mass peak at 3.1 GeV into the shoulder seen in Fig. 1. This peak was found in an improved experiment run in 1974 and named the J/ψ particle⁵. Its interpretation as evidence for the anticipated new quark (the charmed quark) has been discussed in detail elsewhere. In the higher energy experiment carried out at Fermilab in 1975–78, the J/ψ peak is shown in Fig. 2 along with a second interruption to the rational study of the continuum—the upsilon peak near 9.5 GeV. Here again it is generally accepted that a new quark is operating^{6–8}.

Thus, the physics of dilepton production has two components both relevant to the constituent theory of hadrons: (1) the study of the structure functions of the hadrons, dominated by old quarks and (2) the existence, as a very small component, of heavier quarks bearing new internal quantum numbers (flavours).

Fig. 2 Dimuon mass spectrum obtained at FNAL in 1977 showing J/ψ family bumps near 3 GeV and the upsilon peaks near 10 GeV. $-0.3 \leq y \leq +0.3$.

Experimental

After several experiments^{9–10} in which electron pairs were detected^{11,12}, the leptons of choice are muons, principally because of the ease of filtering the enormous flux of hadrons. The earliest muon experiments were hampered by poor resolu-

tion—the result of multiple scattering of the muons in the iron that served as a filter. In the most recent Fermilab research⁶⁻⁸ iron was replaced by beryllium, a compromise which led to a great increase in sensitivity (combination of intensity and resolution). The experiment then consists of a double arm spectrometer which identifies and measures the vector momenta of the two emerging muons. The effective mass is calculated as in equation (2). Other variables of interest are the longitudinal momentum of the parent virtual photon:

$$P_{11} = P_+ \cos \theta_+ + P_- \cos \theta_- \quad (10)$$

and its transverse momentum:

$$P_1 = P_+ \sin \theta_+ + P_- \sin \theta_- \quad (11)$$

We include here data from three groups of experiments. The Fermilab experiments of a Columbia-Fermilab-Stony Brook (CFS) collaboration used 200, 300 and 400 GeV protons on a copper target, a Fermilab experiment which used 225 GeV pions on a carbon target and a group of experiments at the CERN ISR in which protons colliding with protons gave an effective energy of 2,000 GeV proton-proton collisions.

Resonance production

When the bumps are ignored, the data of Fig. 2, are well fitted with a straight line having a mass distribution of the form

$$\frac{d\Gamma}{d\sigma} = A e^{-bm} \quad (12)$$

Subtracting the fitted curve gives Fig. 3. The fitting program then establishes the existence of two peaks Y and Y' at masses of 9.4 and 10.0 respectively. Evidence for a third peak, Y'' at 10.4 is present and has recently been confirmed. A detailed analysis of the experimental resolution established that the peaks are 'narrow'—the observed width is consistent with the experimental smearing of a peak which must then have a width < 100 MeV and could have essentially zero intrinsic width. This single fact requires a new law of nature. A particle as massive as 10 GeV should decay with extremely short lifetime, corresponding to a width of several GeV unless inhibited by a new law. The standard example of an uninhibited decay, is the rho meson which, at 700 MeV of mass, has a width which is 15% of its mass. A detailed investigation of various candidates found in the theoretical literature ruled out all but one possibility: the upsilon is made of new quarks—and is then strongly inhibited from decaying into pions, kaons and so on—particles made of the old up, down and strange (u, d, s) quarks. This essentially repeated the lesson learned in the case of the J/ψ . There, the new (charm) quark hypothesis was resisted until higher energy e^+e^- collisions produced particles in which the charm quantum number was exhibited. (In the J/ψ , it is hidden by a cancellation—the J/ψ is a $c\bar{c}$ bound state.)

Here we should remember the quantum numbers of the old quarks. They are arranged in pairs:

$$\begin{pmatrix} u \\ d \end{pmatrix} \quad \begin{pmatrix} c \\ s \end{pmatrix} \quad (13)$$

The basic distinction is called the flavour—in these pairings, the upper quark has an electrical charge of $+2/3$, the lower one $-1/3$. A proton is primarily a three-quark system (uud), a neutron is (udd). The upsilon changes the picture to:

$$\begin{pmatrix} u \\ d \end{pmatrix} \quad \begin{pmatrix} c \\ s \end{pmatrix} \quad \begin{pmatrix} ? \\ b \end{pmatrix} \quad (14)$$

where the designation b (bottom or beauty) is assigned to the newest quark. The upsilon is then $b\bar{b}$ bound state in this interpretation. The evidence in favour of this interpretation may be summarised as follows:

(1) We have already noted that the FNAL data on the narrowness of the upsilon peak ($\sigma < 100$ MeV) proves the need for a new quantum number. Weak bosons and Higgs particles were ruled out experimentally^{9,10}.

Fig. 3 Upsilon peak with the continuous background subtracted.

(2) The force between quarks, as a basic premise, is supposed to be independent of flavour and carried by quanta of the quark-quark force called gluons. The J/ψ system of particles carrying the c-quark has been analysed in terms of a potential model by Eichten and Gottfried¹³. Using this potential, they calculated that a quark of mass, $m \sim 5$ GeV should give rise to three bound states $1S^3$, $2S^3$ and $3S^3$ of the $b\bar{b}$ system with spacings which are crudely that observed.

(3) Other calculations¹⁴⁻¹⁸ using the $b\bar{b}$ model successfully accounted for the relative strengths of the three levels.

(4) The above conclusions have recently been confirmed in the reaction (4) at the DORIS storage rings. Here, the partial width of the decay

$$Y \rightarrow e^+ + e^- \quad (15)$$

is measured and¹⁹⁻²¹, when compared to theoretical expectations²² establishes the charge $|e_b| = 1/3 e$.

The expectation of partners to the b-quark to replace the ? in equation (14) (called t for top or truth) is very strong. The CFS group has extended the search by collecting ~ 10 times the data that led to the discovery of the upsilon. No more bumps were found and therefore a limit of

$$m_t \geq 8.5 \text{ GeV}$$

could be set by the absence of a bound state, $t\bar{t}$, up to masses of 17 GeV.

Having established the structure of the upsilons as a set of bound states of an 'atom' composed of a massive quark and antiquark, we can learn about the force that produces the binding. This is the primordial strong force, as (see below) our present view of matter is that hadrons are made of quarks glued together by this quark-quark force. (The strong force between protons and neutrons, in this view, becomes a complicated Van der Waal's-type interaction.) Analyses of the upsilon is simplified by the fact that non-relativistic potential theory may be used^{15-18,22}. Literature data indicate that there is a narrow range of potential models that can fit the spectroscopy of both the charmonium and the upsilon energy levels. A very incisive set of data will come from the spectroscopy in the upsilon region and from heavier quark bound states.

The hadrons we know are predominantly composed of u and d quarks. There are traces of s, c, b in decreasing amounts as the masses increase. Nevertheless, without a complete picture of the quark content, an understanding of hadrons is not possible. Clearly an inflation in the number of quarks raises basic questions about elementarity—perhaps six quarks will settle the problem—but already speculations of subquark structures are appearing.

Old quarks: structure functions

The Drell-Yan model (equation (9)), has a simple formulation if we integrate over the motion of the dilepton. As the mass depends only on the momenta of the colliding quarks conservation of energy and momenta permit us to write:

$$x_1 x_2 = \frac{m^2}{s} = \tau \quad (16)$$

$$x_1 - x_2 = x_F \quad (17)$$

$$x_1 = \sqrt{\tau} e^y; x_2 = \sqrt{\tau} e^{-y} \quad (18)$$

Here x_1 is the fraction of the hadron's total momentum carried by the quark 1. Similarly for x_2 . x_F is the longitudinal momentum of the dilepton, m is the mass and s the square of the energy of the collision, evaluated in the CM.

The variable y is often used in place of longitudinal momentum and is known as the rapidity, defined by equation (18).

The aim of the analysis of continuum data is to obtain the structure functions $V(x)$, that is the probability distribution for finding a quark of fractional momentum x . Since there are u and d quarks in a proton, we need $u(x)$, $d(x)$. We note that the proton consists mainly of uud quarks. However, in the old picture of the proton, there was a meson cloud, the virtual presence of mesons, was needed to account for the properties of the proton. In the quark version, the cloud is condensed to a 'sea' of quark-antiquark pairs created by the very strong forces between the main (or valence) quarks. As the sea appears in pairs with no net quantum numbers, we can have $u\bar{u}$, $d\bar{d}$, $s\bar{s}$, $c\bar{c}$, and so on. This accounts for the possibility of producing objects with strange quarks, charmed quarks and so on, in high energy collisions. It also accounts for the presence of antiquarks, required for the Drell-Yan process. Now then, the probability of the production of a dilepton can be written as:

$$\frac{d\sigma}{dm} \propto [V(x_1)S(x_2) + V(x_2)S(x_1)] \quad (19)$$

subject to the condition (16). Here we abbreviate the valence quark distributions by $V(x)$ and the sea quark distributions by $S(x)$.

Fig. 4 Dimuon spectra produced by 200 (■), 300 (▲) and 400 (●) GeV proton collisions

Fig. 5 Test of the scaling hypothesis: at 200 (□), 300 (△) and 400 GeV. All three energies give identical results when $m^2 d\sigma/dm$ is plotted against the dimensionless variable m^2/s .

Now reaction (3), deeply inelastic scattering, also measures $V(x)$ and therefore, the dilepton data of Fig. 2 can be used to determine the sea distribution. A typical result of the fitting program yields a distribution:

$$S(x) = 0.54 (1-x)^{8.5} \quad (20)$$

so that the sea momenta are crowded towards very low values of the fractional momentum. This would be valuable information but the universality of the quark model leads to an even more important conclusion.

There is a reasonable amount of experimental support for the notion that the weak and electromagnetic forces are 'unified'. In older forms, a conserved vector current (CVC) theorem was proposed and tested. The modern version is the theory of Weinberg and of Salam which group the mediators of the weak force, W^+ , W^- , Z^0 and the mediator of the $e-m$ force, γ together into a family. Thus all reactions mediated by a virtual photon should have analogues mediated by the weak boson. Support for this was originally found in weak decays and more recently in neutrino collisions.

The analogue of equation (3) is then

$$\nu + N \rightarrow \mu^- + \text{anything} \quad (21a)$$

or

$$\nu + q \rightarrow \mu^- + q' \quad (21b)$$

for example,

$$\nu + d \rightarrow \mu^- + u$$

Thus neutrino (and anti-neutrino) scattering is also sensitive to quark distributions. Data from Fermilab and CERN have also

been analysed to give the sea distribution. The data agrees well with the results of dilepton production. Here is a subtle detail of the constituent model, the sea distribution of anti-quarks as viewed by two observations (1) neutrinos bringing in virtual W 's to probe the quarks and (2) colliding two hadrons one of which provides a quark to seek out an anti-quark in the other. This is a substantial triumph for the fundamental picture of quark constituents.

The model has another success which has 'practical' applications. One can write the cross-section:

$$\frac{d\sigma}{dm} = \frac{1}{m^3} F(m^2, s) \quad (22)$$

From dimensional arguments F must be dimensionless. Scaling is the assertion that:

$$m^3 \frac{d\sigma}{dm} = F(m^2/s) = F(\tau) \quad (23)$$

that is there are no parameters with energy dimensions which enter. The practical value is that one can use this to predict the yield of masses at future accelerators from results at hand. Example: At FNAL, $s = 750 \text{ GeV}^2$ and the yield of 15 GeV dileptons is known. Thus at a future accelerator, such as ISABELLE, $s = 160,000 \text{ GeV}^2$, one would expect the same value of F for $m = 200 \text{ GeV}$. Because m is the mass of a virtual photon, the predictions can be applied to all states which can connect to photons: pairs of massive leptons, W bosons, quarks, monopoles, and so on.

The test of the scaling hypothesis is indicated in Fig. 4 where a fit to the Fermilab data at 200, 300 and 400 GeV (consistent with scaling but over too small a range to be decisive) is extended to 2,000 GeV and compared to ISR ($s = 3,600 \text{ GeV}^2$) results^{23,24}. To the level of ~20% the agreement is good. The fit that was found is:

$$F(\tau) = 44.4 \exp(-26.6 \tau^{1/2}) \times 10^{-30} \text{ cm}^2$$

Another success of the model becomes evident in the Fermilab experiments of a Chicago-Princeton collaboration²⁵ who use pions as the incident particle. A negative pion is a tid combination of quarks. Thus the anti-quark is part of the valence population. Qualitatively this means that dilepton production should be much easier there would be no need to search the sea for antiquarks. Indeed the probability for continuum dilepton production near 10 GeV of mass is more than 200 times bigger for incident pions. As a further benefit, the structure function for the valence quarks of the pion have been determined from the same experiment—so a photograph of the pion is now at hand. As the pion lives only 10^{-8} s and is created in high energy collisions, this is another major achievement. The form of the pion structure function (in momentum space) is:

$$u(x) \approx (1-x)^{1.13} \quad (24)$$

the quark momenta in the pion fall only linearly with x .

Quantum chromodynamics

Given this quantitative success (at the 20% level), it is clear that the next few years will lead to refinements and more incisive tests of the model. At this point we should note that the model has become a theory: quantum chromodynamics (QCD) deals with the quantum field theory of the quark-quark strong force in close analogy to QED. Thus the force between quarks is carried by vector gluons which are also an ingredient of the sea. Being neutral they do not interact directly with photon probes but their ability to scatter with quarks and among themselves leads to corrections to the quark model. Some of these effects have been observed in deeply inelastic scattering as violations of scaling in those experiments. That is, experiments at Fermilab²⁶ using high energy muons have established that reaction (7) is not true but that, in the higher Q^2 domain one must write $F(x, Q^2)$. These same corrections, in the dilepton production data we have

Fig. 6 A comparison of QCD calculations (due to Berger) with the data on transverse momentum of dileptons. We see the infrared difficulties of the present status of the QCD theory, also the theory needs an additional component: intrinsic quark motion: $7 \leq M \leq 8 \text{ GeV}$, $y = 0$; —, total; — — —, Compton; — — — —, annihilation.

discussed are small. However, they show up in a surprising way. There is one aspect of the data which is wholly determined by the QCD effects.

High transverse momentum dileptons

In the quark-parton model the hadron is viewed as a cluster of parallel moving point-like partons. If two annihilate, the resulting dilepton should also move longitudinally. Even the earliest observations¹ indicated that there is a large transverse momentum component to the dilepton. In the context of the model this implies that the annihilating quarks must bring in the transverse momentum. In the confrontations of theory and data, (see Fig. 6) and in the subsequent evolution of the applications of QCD it became clear that QCD contained just the necessary ingredients: one source of quark transverse momentum has to do with dynamical processes contributing to the production of the lepton pair²⁷⁻³³. These processes involving both quarks and gluons could account qualitatively for the observations. Quantitative comparisons with experiment were used to tune the parameters of the theory—most sensitively, the momentum behaviour of the gluons. However, not all the observed effects were produced until an intrinsic transverse momentum was involved. This microcosmic Fermi motion is closely related to the size effect of the confining force.

Thus the transverse momentum of dileptons provides both a basic challenge to the theory and a source of information on the constituent behaviour. Although it is not clear how quantitatively valid the QCD calculations are, we know qualitatively that they give a good account of the high P_T dilepton data, using terms which are required to understand scaling violations observed in reaction (3). The prospects are very encouraging and the issues are crucial. QCD is the first quantum field theory of hadrons. Progress is sporadic and problems in the calculations abound. For example, Fig. 6 shows the infrared divergence of the P_T calculations. Nevertheless, the stakes are high and the advance of the experimental techniques in dilepton physics will provide even more incisive data to confront and guide the developing theory.

Geochemistry of basalts from the Tyrrhenian Sea

Bruno Hamelin, Bernard Lambret, Jean-Louis Joron, Michel Treuil & Claude J. Allègre

Laboratoire de Géochimie et Cosmochimie (LA 196), Institut de Physique du Globe et Département des Sciences de la Terre, Universités de Paris VI et VII—2 Place Jussieu 75230 Paris 05, France

Comparison between the Tyrrhenian basalts and oceanic basalts coming from different geodynamic environments shows that Tyrrhenian basalts have a clear organic signature with a transitional character.

THE genesis of the western Mediterranean oceanic floor is still poorly understood¹, and the origin of the Tyrrhenian Sea (Fig. 1) is a matter of conjecture. What kind of basement lies underneath—thin continental crust, intermediate crust, or true oceanic crust? Recent studies^{2,3} have interpreted the Tyrrhenian Sea as a marginal one⁴.

The DSPD leg 42 A site 373 A drill hole provided, for the first time, fresh material from the Tyrrhenian Sea floor. This material is basaltic and has recently been described from a petrological point of view^{5,6}. This article presents the results of a geochemical study including strontium and lead isotope compositions and trace elements (including rare earths) concentrations of seven samples representing different stratigraphic positions⁷. These results will permit comparison with the basalts erupted in different geodynamic environments, and are identical to patterns expected for transitional basalts.

Experimental techniques

The strontium isotopic compositions, as well as K, Rb and Sr concentrations, have been determined by mass spectrometry and isotope dilution using the method described elsewhere⁷. The concentrations of these elements are known with an accuracy of 1%. We used the NBS 987 standard and our data are normalised to a ⁸⁷Sr/⁸⁶Sr ratio of 0.7014 ± 0.00007 (2σ) for this standard.

The lead isotopic composition was measured using the Manhes microtechnique⁸. The blanks range from 0.9 to 3.5 ng per 1 g of sample powder. Accuracy of the isotopic measurement is limited by mass fractionation which was found to be 0.1% per mass unit by repetitive analyses of the SRM 982 standard. Data are normalised to the accepted ratios of this standard which are: ²⁰⁴Pb/²⁰⁷Pb = 0.05845, ²⁰⁶Pb/²⁰⁷Pb = 2.1433, ²⁰⁸Pb/²⁰⁷Pb =

Fig. 1 Location of leg 42 site 373 A. Darkened regions are areas of Italian and Sicilian volcanism.

$^{87}\text{Sr}/^{86}\text{Sr}$	0.70321	0.70292	0.70313	0.70299	0.70300	0.70300	0.70306
$^{206}\text{Pb}/^{204}\text{Pb}$	±0.00010	±0.00009	±0.00012	±0.00012	±0.00010	±0.00009	±0.00007
$^{207}\text{Pb}/^{204}\text{Pb}$	18.874	18.657				18.774	18.848
$^{207}\text{Pb}/^{204}\text{Pb}$	±0.013	±0.020				±0.023	±0.015
$^{207}\text{Pb}/^{204}\text{Pb}$	15.613	15.567				15.567	15.600
$^{207}\text{Pb}/^{204}\text{Pb}$	±0.015	±0.021				±0.022	±0.017
$^{208}\text{Pb}/^{204}\text{Pb}$	38.62	38.47				38.52	38.59
$^{208}\text{Pb}/^{204}\text{Pb}$	±0.02	±0.08				±0.02	±0.05

Quoted errors for lead data are $(\sigma^2 + (\delta_m R)^2 \cdot \sigma_s^2)^{1/2}$ where σ is the uncertainty in the run, and σ_s the error on the discrimination factor, estimated from repeated measurements of SRM 981 standard, R is the measured ratio and δ_m the mass difference in this ratio. Measured ratios of one basalt from the Lau basin are: $^{206}\text{Pb}/^{204}\text{Pb} = 18.322$; $^{207}\text{Pb}/^{204}\text{Pb} = 15.521$; $^{208}\text{Pb}/^{204}\text{Pb} = 38.020$.

2.1393. No measured value differs from this average by more than 0.4% for $^{204}\text{Pb}/^{207}\text{Pb}$, which can be considered as an upper limit for error.

The trace element concentrations (other than K, Rb and Sr) have been measured by epithermal neutron activation analysis, following the technique described by Treuil *et al.*⁹. The rare earths were measured after chemical separation, the other elements by direct instrumental analysis. Results and uncertainties for each element are given in Table 1.

Results and interpretations

The $^{87}\text{Sr}/^{86}\text{Sr}$ isotopic ratios are fairly constant (0.7031) (Table 2) and higher than the typical mid-oceanic ridge basalt values, which are between 0.7022 and 0.7028 (refs 10, 11); they are also higher than the few values obtained on interarc basin tholeiites (Lau Basin¹¹ and Mariana Trough^{12,13}). These results are very

similar to the 'abnormal or transitional MORB', like the Reykjanes Ridge near Iceland^{14,15} or the FAMOUS area^{16,17}. On the other hand, the values are much lower than those of the Eolian basalts (0.7049 to 0.7065)¹⁸ and Italian volcanic rocks analysed by Vollmer¹⁹, although similar to the values on the eastern Sicilian volcanics²¹ (Etna and Iblean basalts).

The lead isotopic compositions (Table 2, plotted on a $^{207}\text{Pb}/^{204}\text{Pb}$ versus $^{206}\text{Pb}/^{204}\text{Pb}$ diagram in Fig. 2) fall just above the 'MORB quadrangle' defined by Sun²², as do the FAMOUS area samples (Dupré and C.J.A., in preparation, and Cumming²³). These basalts have $^{206}\text{Pb}/^{204}\text{Pb}$ ratios similar to those of the Icelandic basalts, but slightly higher $^{207}\text{Pb}/^{204}\text{Pb}$ ratios^{15,24}, and are also within the domain of some island arc volcanics^{25,26}. Moreover, they are clearly different from the Italian volcanic rocks¹⁹, as well as from the Sicilian and Etna basalts²¹, which show the high $^{207}\text{Pb}/^{204}\text{Pb}$ typical of rocks

Fig. 2 Lead-strontium correlation diagram discussed by Vollmer¹⁹. The Tyrrhenian basalt results (□) are clearly off the mixing trend between Italian volcanic rocks (Δ) and Sicilian and Etna basalts (●).

including crustal material. The few data obtained on marginal basins (Mariana Trough¹³, and one sample from the Lau Basin, Table 2) give typical ridge values.

The Ni and Cr content of basalts which are direct products of partial melting of the mantle are around 220 to 350 p.p.m. for Ni, and 500 p.p.m. for Cr (refs 27, 28). Such values decrease rapidly when the basalts suffer shallow fractionation²⁸. The values of Ni, Cr and Co (Table 1) show clearly that these basalts are not very primitive and have undergone some fractional crystallisation before their eruption on the ocean floor. Therefore, data on trace element levels should be used with caution in attempts to infer the nature of the primitive material. However, findings for the magmatophile elements²⁹, which are the least affected by fractional crystallisation, lead to several interesting points. The K/Rb ratios are similar to those of MORB (~1,000) and clearly higher than values for alkali basalts³⁰: this is true in spite of the high content in Cs (for at least three of the analysed samples), which is a very good alteration indicator. Alteration could have lowered the K/Rb and K/Cs ratios, and raised the K content and ⁸⁷Sr/⁸⁶Sr ratio³¹ (see, for example, sample 7). It is likely that these characteristics have not been greatly affected,

however, as we observe no correlation between the Cs and K contents and K/Rb or Sr isotopic ratio, and as these values are the same for the samples with low Cs content.

The rare earth patterns are very constant, although the absolute concentrations vary. The patterns are light rare earth enriched, very different from typical MORB which show light rare earth depletion. Such a distribution is very similar to the transitional MORB type, like some Icelandic tholeiites or the basalts dredged in the FAMOUS area³². On the other hand, the Tyrrhenian basalt patterns are very similar to those found by Hart *et al.*¹³ in the Mariana Trough.

Th and Ta are incompatible elements and therefore their ratios are not greatly affected by fractional crystallisation and partial melting²⁹. One of the very interesting properties of this ratio is the clear distinction in signature between subduction zone volcanics and oceanic volcanics. The Ta/Th ratio of subduction zone volcanics, like Japan or the Eolian islands, is very low (0.1) whereas the oceanic type like the mid-Atlantic Ridge, Red Sea or FAMOUS area, is between 0.6 and 1.2. The basalts from the Tyrrhenian Sea are clearly of the 'oceanic' type.

The Tyrrhenian Sea is a relatively recent (7.3 Myr)³ and rather small sea, bordered by two important cratons, so these results suggest that the development of small or marginal seas may generate oceanic crust containing basalts of transitional character. Such characteristics are different from the marginal sea types associated with subduction zones which are, so far, not very different from typical MORB.

Fig. 3 Chondrite normalised rare earth abundance. The values are similar to those of transitional basalts, like those of the FAMOUS area³². The positive Eu anomaly can be attributed to the presence of plagioclase phenocrysts³.

We can try to incorporate our results into the isotopic picture given by Vollmer¹⁹ for the Italian province. As shown in Fig. 2, the Tyrrhenian basalts do not follow the general trend found for the Italian volcanics. We can perhaps define a trend between Etna and Tyrrhenian basalts. Therefore, the petrogenesis of the Italian volcanic province may be explained by the mixing between oceanic island type magma and the continental crust¹⁹ (such an interaction is very similar to a rift valley-type volcanism, for example), although it may not be due to a subduction process. The Etna volcanism may be a result of interaction between the same oceanic island type magma and a mid-oceanic ridge type one.

Local aggregation of hormone–receptor complexes is required for activation by epidermal growth factor

Yoram Schechter*, Lydia Hernaez*, Joseph Schlessinger† & Pedro Cuatrecasas*

* Department of Molecular Biology, The Wellcome Research Laboratories, Research Triangle Park, North Carolina 27709

† Department of Immunology, the Weizmann Institute of Science, Rehovot, Israel

An analogue of epidermal growth factor (EGF) which is virtually devoid of biological activity retains receptor binding activity but cannot form cell surface clusters or patches. Bivalent anti-EGF antibodies restore both bioactivity and patch formation. The sensitivity of fibroblasts to native EGF can also be enhanced greatly by these antibodies, especially in hormone-resistant cell lines.

EPIDERMAL GROWTH FACTOR (EGF) is a single-chain polypeptide hormone of molecular weight ~6,000. The hormone was isolated from the male mouse submaxillary gland¹ and found to be a potent mitogen of various epidermal and epithelial tissues both *in vivo* and *in vitro*^{2,3}. It can stimulate the proliferation of various cultured cells such as human fibroblasts⁴, glial cells⁵, granulosa cells⁶ and mouse 3T3 cells⁷. Carpenter and Cohen have presented data which suggest that the binding of EGF to human fibroblasts is followed by internalisation and degradation, presumably by lysosomal enzymes⁸. Using fluorescently labelled, biologically active analogues of EGF and insulin⁹, it has been shown by fluorescent photobleaching recovery that the surface-bound hormone molecules can diffuse laterally in the plane of the membrane with a diffusion coefficient (D) of $3-5 \times 10^{-10} \text{ cm}^2 \text{ s}^{-1}$ (refs 9, 10). Fluorescence microscopy studies have shown that these hormones are initially bound diffusely on the cell surface, and at 4 °C they remain dispersed for at least 90 min (ref. 11). Within a few minutes of warming the cells to 37 °C, the hormones aggregate into patches. The visible, clustered hormone molecules are subsequently (within half an hour) internalised by endocytic vesicles. Although it has been tempting to try to relate these processes of redistribution, internalisation and degradation to the mode of action of these hormones, the physiological significance of these events has not been established.

We have recently presented data which indicate that the stimulation of DNA synthesis in fibroblasts by EGF depends on the persistent occupation of a relatively small fraction of the total measurable, externally located binding sites for the hormone¹². The enhancement of DNA synthesis observed 24 h after the addition of EGF is completely blocked by adding anti-EGF immunoglobulin at any time during the first 8–10 h of incubation, indicating the need for the continued presence of externally located molecules¹².

The studies described here suggest that hormone–receptor complexes must undergo some type of cell surface redistribution and self-aggregation to elicit a biological response. Cleavage of EGF with cyanogen bromide results in a unique hormone derivative (CNBr-EGF) which is virtually devoid of biological activity but which nevertheless retains substantial (10%) binding activity. The biological activity of this inactive analogue can be restored by cross-linking with specific bivalent antibodies to EGF. Also, concentrations of native EGF far below those that

Fig. 1 Competition of binding of labelled native EGF by EGF and various derivatives. 3T3 fibroblasts in monolayers (approximately 3×10^5 cells, 100 μg of protein) and ^{125}I -EGF (1.4 ng ml^{-1} , 300,000 c.p.m. per ng) were incubated with various concentrations of native EGF (purified from mouse submaxillary glands as described in ref. 13) or its derivatives in 0.5 ml medium containing 0.1% bovine serum albumin (BSA) for 45 min at 37 °C. Unbound radioactivity was then removed by washing four times with cold Hank's solution–0.1% BSA. The cells were solubilised with 1.0 ml of 1.0 M NaOH and the radioactive content was determined. The amount of bound radioactivity was 6,000 c.p.m. per well in the absence of unlabelled hormone. ○, Native EGF; ●, native EGF which had been incubated in 70% formic acid for 24 h; ▲, R-EGF; □, CNBr-cleaved EGF; ■, R₂-CNBr-cleaved EGF.

normally show activity can elicit dramatic responses on addition of anti-EGF antibody. Furthermore, cells that are relatively refractory to EGF, despite unimpaired binding, can be markedly 'sensitised' to respond by cross-linking the cell-bound native EGF with antibody. Clearly, hormone binding alone is a biologically unproductive process without a subsequent step of micro-redistribution, aggregation or cross-linking which seems to be a limiting, determining process.

CNBr-EGF: a biologically inactive analogue antagonistic for EGF binding but not activity

EGF has a single methionyl residue at position 21 (ref. 1), and cleavage with cyanogen bromide results in the formation of two polypeptide chains connected by the disulphide bonds of the protein molecule. The binding and biological properties of CNBr-EGF are presented in Fig. 1 and Table 1. Cyanogen bromide-cleaved EGF inhibits the binding of ^{125}I -EGF to 3T3 fibroblasts at concentrations approximately one order of magnitude higher than the native hormone. However, CNBr-EGF only has 0.3% or less of the activity of the native hormone in stimulating thymidine incorporation (DNA synthesis) into

confluent 3T3 fibroblasts. The analogue therefore exhibits at least a 30-fold disparity between its affinity for binding and for biological activation.

The biological and binding properties of the other derivatives used in the present studies are also presented in Table 1 and Fig. 1. Labelling of CNBr-EGF with two molecules of rhodamine (R), to produce R₂-CNBr-EGF, does not result in significant further changes in the properties of this derivative. Exposure of native EGF to the same conditions used in the preparation of CNBr-EGF slightly reduced the binding affinity and biological activity (Table 1).

Cyanogen bromide-cleaved EGF retains 10% of its antigenic activity as determined by radioimmunoassay (see legend to Fig. 2). Half-maximal inhibition of ¹²⁵I-EGF precipitation in this assay is obtained at 50 ng per assay compared with a value of 5 ng per assay obtained with the native hormone.

Anti-EGF antibodies restore the activity of CNBr-EGF

When 3T3 cells are incubated with CNBr-EGF and anti-EGF IgG is then added, full restoration of biological activity can be obtained. Figure 2 shows a typical experiment in which the cells were first incubated with 5 ng ml⁻¹ of the derivative and then with various concentrations of anti-EGF IgG. Full restoration of activity is limited to a narrow range of concentration of the antibody (1:10,000–1:8,000 of the antibody solution, A₂₈₀ = 3.1). No restoration of activity occurs at higher or lower concentrations or when monovalent Fab' derived from anti-EGF IgG is combined with the hormone derivative (Fig. 2). This fragment has about 80% of the capacity of anti-EGF IgG to precipitate ¹²⁵I-EGF in a double antibody immunoassay. Anti-EGF IgG has no effect on DNA synthesis in the absence of the hormone derivative, and an IgG fraction from normal rabbit serum is inactive either alone or in combination with CNBr-EGF.

Fig. 2 Biological activity of CNBr-cleaved EGF in the presence of various concentrations of anti-EGF-IgG. Thymidine incorporation into confluent 3T3 monolayers was carried out in the presence of CNBr-cleaved EGF (5 ng ml⁻¹) and the indicated antibody dilutions prepared from purified anti-EGF immunoglobulin fraction (A₂₈₀ = 3.1). The cells were incubated with the hormone derivative for 20 min at room temperature before adding the antibody. The cells in this experiment produced half-maximal stimulation at EGF concentrations of 0.15 ng ml⁻¹. Maximal thymidine incorporation was 400% of control values in the absence of added mitogen. Monovalent Fab' was prepared by papain digestion of anti-EGF-IgG (ref. 15). The Fc fragment and the undigested IgG fraction were removed by a Sepharose-protein A affinity column (Pharmacia) and the non-retarded fraction was subjected to reduction with 5 mM dithiothreitol at pH 8.5 for 30 min. Iodoacetamide was then added (0.01 M final concentration) and after 20 min the sample was dialysed overnight against 0.05 M sodium phosphate (pH 7.5) at 4 °C; CNBr-EGF combined with anti-EGF-IgG (A₂₈₀ = 3.1) (●); CNBr-EGF combined with monovalent Fab' fragment derived from anti-EGF-IgG (○). By radioimmunoassay CNBr-EGF retains 10% activity, as determined by a standard 'double antibody' radioimmunoassay using anti-EGF-IgG fraction (A₂₈₀ = 3.1) as the 'first antibody' at a final dilution of 1:5,000. Anti-EGF-IgG was purified¹² from rabbit anti-EGF serum; this was used rather than anti-EGF serum as the latter has intrinsic DNA-stimulating activity¹².

Table 1 Binding and biological activities of various EGF derivatives

EGF or derivative	Binding affinity to cells		Biological activity	
	50% ¹²⁵ I-hormone displacement (ng ml ⁻¹)	Relative binding potency (%)	ED ₅₀ (ng ml ⁻¹)	Relative activity (%)
EGF	0.8	100	0.13	100
EGF treated with 70% formic acid	1.0	80	0.15	87
R-EGF	1.3	61	0.24	54
CNBr-EGF	10	8	50	0.3
R ₂ -CNBr-EGF	12	7	60	0.2

3T3 fibroblasts were plated at 10⁵ cells per dish in 1 ml of modified Eagle's medium with HY-Clone 10% fetal bovine serum (Sterile System) in 35-mm plastic tissue culture dishes. Incubations were carried out at 37 °C under 90% air, 10% CO₂ humidified atmosphere. The cells were fed after 24 h and used after 96–120 h. Thymidine incorporation into confluent monolayers was measured as described previously¹⁴ using a 2-h pulse with 1 μCi ml⁻¹ of [methyl-³H]thymidine started 24 h after the addition of the mitogen. CNBr-EGF was prepared by treating EGF (1 mg ml⁻¹) containing a trace quantity of ¹²⁵I-EGF in 70% formic acid with 400–500 equivalents of crystalline cyanogen bromide (Fluka) for 24 h at room temperature. The solution was then evaporated under vacuum and the residue redissolved in H₂O and lyophilised. Native EGF, with no cyanogen bromide added, was treated similarly. An acid hydrolysate of the derivative contained no methionine and about 1 mol of homoserine or its lactone. Details of the preparation of the fluorescent derivatives is given in the legend to Fig. 3. Experimental values for binding affinity were obtained from Fig. 1. The relative binding potency is the concentration of native EGF or derivative that inhibits 50% of the binding of ¹²⁵I-EGF. The ED₅₀ is the concentration of EGF that produces half-maximal stimulation of DNA synthesis. R-EGF = native EGF labelled with one molecule of rhodamine; R₂-CNBr-EGF = CNBr-EGF labelled with two molecules of rhodamine.

These data suggest that the hormone receptors occupied by CNBr-EGF are ineffective because of their inability to induce receptor redistribution and aggregation, and that this deficiency can be corrected by passively cross-linking the CNBr-EGF-occupied receptors with bivalent (but not monovalent) antibody. This hypothesis was explored further by fluorescence microscopy studies.

Distribution of fluorescent analogues of EGF on the cell surface

It was previously reported that in 3T3 cells exposed to rhodamine-labelled EGF (R-EGF) the hormone-receptor complexes are homogeneously distributed at 4 °C whereas at 37 °C they rapidly cluster and form visual patches on the cell surface^{11,16}. When 3T3 cells are incubated with 200 ng per ml of CNBr-EGF labelled with two molecules of rhodamine (at each of its two amino-terminal groups) (R₂-CNBr-EGF) for 45 min at 4 °C, the hormone complexes are also diffusely distributed on the cell membrane (not shown). In contrast to the results with R-EGF, incubation at 37 °C for 1 h or more does not cause any visible clustering, and staining remains diffuse (Fig. 3a, b). However, visual patches are readily seen when anti-EGF antibodies are added to cells labelled with R₂-CNBr-EGF (Fig. 3c, d). These visual patches are observed with antibody dilutions of 1:10–1:100 but not at higher (1:120–1:20,000) dilutions.

These data further confirm that, unlike the native hormone, CNBr-EGF has lost its ability to self-aggregate spontaneously at 37 °C, even at high receptor occupancy and after prolonged periods of incubation. This deficiency can be at least partially corrected by antibody to EGF. Visible patches are not, however, observed at the range of antibody concentration in which the biological activity of CNBr-EGF is restored (see previous section). It is thus possible that microaggregates (which may be composed of two or several hormone-receptor complexes), rather than large clusters or aggregates, are the 'state of microaggregation' responsible for triggering biological activity. It is not possible, however, to determine whether some macroaggregates of the type visualised at high receptor occupancy with R-EGF can also form at low receptor occupancies.

Fig. 3 Distribution of R_2 -CNBr-EGF on the cell surface of 3T3 fibroblasts in the presence and absence of anti-EGF-IgG. *a* and *b* describe the phase and fluorescence micrographs, respectively, of the same field ($\times 1,950$) of 3T3 cells which were incubated for 30 min at 37°C with 200 ng per ml of R_2 -CNBr-EGF. The cells were then washed with phosphate-buffered saline (PBS)-1% BSA, fixed with 1% formaldehyde, and observed with an image-intensified video fluorescent microscope as described previously¹¹. The level of nonspecific fluorescence was determined as described¹¹, and found to be about 30% of the total fluorescence intensity. R_2 -CNBr-EGF was prepared by reacting CNBr-EGF (1 mg) containing a trace quantity of ^{125}I -CNBr-EGF in 1 ml of 0.2 M sodium carbonate buffer (pH 9.3) with three aliquots (20 μl each) of a solution (10 mg ml^{-1}) of rhodamine isothiocyanate (Research Organic Chemicals) in dimethylformamide. Excess reagent was removed by gel filtration on a Sephadex G-15 column. R-EGF was prepared in a similar manner, starting from native EGF (1 mg) containing a trace quantity of ^{125}I -EGF. The ratio of $^{125}\text{I}/A_{545}$ was used to determine the extent of the reaction as previously described⁹. R-EGF and R_2 -CNBr-EGF contained about 1 and 2 mol of rhodamine per mol EGF, respectively. Their biological properties are given in Table 1. *c* and *d* describe the phase and the fluorescence micrographs, respectively, of the same field ($\times 1,950$) of cells prepared as described above except that the cells were incubated for an additional 30 min at 37°C with anti-EGF-IgG (final dilution of 1:50 from a stock solution of the antibody, $A_{280} = 3.1$) before fixation with formaldehyde.

Antibody enhancement of native EGF activity in sensitive and resistant cells

In view of the above findings, we examined the possibility that antibodies might enhance the activity of very low, sub-optimal concentrations of native EGF. In these conditions, it is theoretically possible that the density of active EGF-receptor complexes is sufficiently low to limit the probability and extent of cross-linking in a way that may be enhanced by bivalent antibody. Indeed, although antibodies have virtually no enhancing effects on low but slightly active concentrations (1 pg ml^{-1}) of native EGF, a definite effect on inducing the emergence of activity can be observed when lower concentrations (0.1 pg ml^{-1}) of the hormone are used (Fig. 4*a*).

As these studies were carried out on cells which are highly sensitive to EGF and whose receptors are not expected to be defective in the property of self-aggregation when occupied by the hormone, we examined cells containing unaltered numbers of EGF binding sites but which were relatively insensitive to the hormone (Table 2). It was reasoned that the receptors in these cells could theoretically be relatively defective in the property of

self-aggregation, so that artificial, exogenous cross-linking with antibody might induce even more dramatic effects. As we consistently observed that 3T3 cells of low passage are more sensitive to the effects of EGF, and that with increasing passage there is a progressive loss of sensitivity, despite the fact that the numbers of EGF binding sites do not change, high-passage or 'poorly responsive' 3T3 cells were studied (Table 2, Fig. 4*b*). In these cells addition of anti-EGF IgG results in a dramatic restoration of the activity at all concentrations of the hormone. Highly significant biological effects are observed at EGF concentrations as low as 0.1 pg ml^{-1} , which is three to four orders of magnitude lower than the concentrations normally required to produce half-maximal effects in these cells. As observed for CNBr-EGF, monovalent Fab' is without effect (Fig. 5*b*). Note that quantitative differences exist between the restoration of activity of CNBr-EGF (Fig. 2) and that observed with submaximal doses of the native hormone (Fig. 4). The restoration is more complete for CNBr-EGF and it is restricted, for unknown reasons, to a narrower range of concentration of antibody. It is also pertinent that substantially lower concentrations of EGF are required to elicit activity in sensitive compared with resistant cells (Table 2). These results also suggest that the loss of hormone responsiveness observed with increased cell passage may be related to the modification of a process which restricts hormone-receptor mobility or self-aggregation.

Fig. 4 Biological activity of submaximal concentrations of native EGF using various concentrations of anti-EGF-IgG in 'highly responsive' (*a*) and 'poorly responsive' (*b*) 3T3 cells. *a*, Thymidine incorporation was carried out with 0.1 pg per ml ($\blacktriangle$) and 1 pg per ml ($\bullet$) of EGF and the indicated dilutions of a solution of purified anti-EGF-IgG ($A_{280} = 3.1$). The cells were incubated with the hormone for 20 min before the addition of antibody. The cells in this experiment (passage 2) produced half-maximal stimulation at EGF concentrations of 7–10 pg ml^{-1} . Maximal thymidine incorporation was 650% of control values without added mitogen. 0.1 pg per ml ($\triangle$) and 1 pg per ml ($\circ$) of EGF in the absence of anti-EGF-IgG. No effect of the antibody was detected at higher concentrations of the hormone (5 and 10 pg ml^{-1} , not shown). *b*, Thymidine incorporation was carried out with 0.1 pg per ml ($\triangle$), 1 pg per ml ($\bullet$) and 10 pg per ml ($\circ$) of native EGF and the indicated dilutions of purified anti-EGF-IgG ($A_{280} = 3.1$). The cells in this experiment (passage 14) produced half-maximal stimulation at EGF concentrations of 1 ng ml^{-1} . Maximal thymidine incorporation was 250% of control values without added mitogen. $\square$, Native EGF (10 pg) in the absence of anti-EGF-IgG; $\blacktriangle$, EGF (10 pg) plus monovalent Fab'.

Table 1 Comparison of some properties of 3T3 cells 'poorly responsive' or 'highly responsive' to EGF

Cell type	Passage no.	No. of binding sites	Binding affinity	ED ₅₀	% Thymidine incorporation
Highly responsive	2-5	40,000-70,000	2.5-4.0	5-20	600-1,100
Poorly responsive	12-26	40,000-70,000	2.5-4.0	1,000-2,000	170-250

Binding affinity is the concentration of ^{125}I -EGF ($\times 10^{10}$ M) required to achieve half-maximal binding, determined by incubating 3T3 cells in monolayer with increasing concentrations of ^{125}I -EGF (300,000 c.p.m. per ng) for 45 min at 37 °C, as described in ref. 14. The ED₅₀ is the concentration (pg ml⁻¹) of EGF producing half-maximal stimulation of DNA synthesis. Thymidine incorporation is expressed as the per cent stimulation with maximal concentrations of EGF compared with that in the absence of the mitogen (100%).

Mechanisms which involve self-aggregation require lateral mobility of receptor sites in the plane of the plasma membrane. This was predicted earlier^{17,18} and demonstrated recently for EGF and insulin receptors of 3T3 fibroblasts^{9,10}. The significance of receptor-receptor aggregation has previously been suggested in receptor-mediated processes as well as in other biological systems. Kahn *et al.* have shown that antibodies to insulin receptors (obtained from patients with insulin-resis-

tant diabetes) can mimic insulin in stimulating glucose oxidation in adipocytes^{19,20}. The Fab' fragment derived from these antibodies competes with ^{125}I -insulin for binding but does not stimulate glucose oxidation. However, cross-linking with anti-Fab' antisera restores activity²⁰. Antibodies raised against the purified insulin receptor²¹, and plant lectins which are known to bind to insulin receptors²² may also produce biological responses by cross-linking insulin receptors. Conditions which cause degranulation of mast cells and basophils also cause clustering of Fc receptors²³. When B lymphocytes, which contain immunoglobulin molecules as an integral component of the plasma membrane, interact with bivalent antigens, they are triggered to proliferate and differentiate²⁴.

The present studies could have important applications to other polypeptide hormone systems. For example, in certain types of insulin-resistant diabetes, or other similar states, defects may exist that impair receptor self-aggregation.

Note added in proof: Anti-insulin antibodies have now also been shown to enhance substantially the biological effects of this hormone on fibroblasts²⁵. Although this effect is accompanied by an increase in the apparent affinity of binding of insulin, in the case of EGF, antibodies do not significantly increase the binding of this hormone to fibroblasts or liver membranes²⁵.

Circular polarisation and the magnetic dipole model

THE magnetic dipole model for a compact extragalactic radio source proposed by Sanders^{1,2} and discussed by Milgrom and Bahcall³ and by Sanders and DaCosta⁴, accounts for one of the features observed in a few of these sources—the apparently superluminal separation of two components (see ref. 5). However, the magnetic dipole model requires a strong, well-ordered magnetic field and predicts that the radio emission will have a substantial degree of circular polarisation unless the double source appears highly symmetric to the observer, or the radiation is by positrons and electrons in nearly equal numbers. For the past five years we have been monitoring extragalactic variable radio sources for circular polarisation at 8 GHz, and we have recently begun observations at 4.8 GHz. We present evidence here that the circular polarisation observations made by us and by other observers conflict with the predictions of the magnetic dipole model.

Our circular polarisation monitoring program and the observing procedure has already been described⁶. Averages for all our observations of several sources at 8 GHz between

October 1973 and October 1978 are presented in Table 1. The standard deviations are based on the scatter of the observations about their mean values and therefore reflect any possible

Table 1 8.0 GHz circular polarisation measurements October 1973 to October 1978

variations. Four bright radio sources have exhibited superluminal expansion⁵: 3C120, 3C273, 3C279 and 3C345. The degrees of circular polarisation which we have observed at 8 GHz for these and other sources have been less than or about 0.1% (ref. 6 and Table 1). Degrees of circular polarisation up to a few tenths of a per cent have been detected by other observers at lower frequencies (see refs 7–9). We have detected variations in the circular polarisation from at least two sources, 3C84 and 3C273 (ref. 6). Figures 1–3 show monthly averages of the total flux densities and degrees of circular polarisation at 8 GHz for 3C273, 3C279 and 3C345 respectively. Smoothing cubic splines¹⁰ have been fitted to the data. Throughout the period of observation the degree of circular polarisation did not rise substantially above ~0.1%.

In the magnetic dipole model^{1–4} the relativistic electrons stream out along the magnetic field lines with moderately small pitch angles during an outburst. The required magnetic field strengths must be at least the equipartition value to maintain the geometry of the field. The four sources which have shown superluminal expansion have estimated equipartition magnetic field strengths of about 0.1–1 G (ref. 11). Fields of this strength and pitch angles of 20°–30° yield 1–3% circular polarisation at 8 GHz for a transparent synchrotron source¹². (Sanders and DaCosta⁴ suggest larger magnetic fields and smaller pitch angles, which would increase the degree of circular polarisation to 10–15%.) In contrast, very long baseline interferometry (VLBI) indicates typical values of $\leq 10^{-3}$ G for the transverse component of the magnetic field $B_{\perp}$ in these sources¹³. This can be reconciled with the equipartition values if the pitch angles are quite small, $\leq 10^{-3}$ rad, which would produce degrees of circular polarisation approaching 100%¹⁴.

As Sanders and DaCosta⁴ pointed out, no circular polarisa-

Fig. 2 As Fig. 1 but for 3C279.

tion would be produced if the radiation were generated by comparable ensembles of electrons and positrons. The following discussion considers the case when the radiation is primarily by electrons, so that the individual source components would be highly circularly polarised.

A significant degree of cancellation of the circular polarisation is expected in the magnetic dipole model because the magnetic field points towards the observer in one component and away from the observer in the other component, so that the sense of circular polarisation will be opposite in the two components^{1,4,12}. The net circular polarisation will, in general, still be non-zero because the total flux densities and magnetic field strengths of the two emitting regions are not expected to be identical. For an observer out of the equatorial plane of the dipole (as is required for separation rates in excess of 4.4c), the magnetic fields and pitch angles in the two components would be different even if the dipole geometry were perfectly symmetrical³. The polarised flux densities of the two components must differ by less than about 10% to be consistent with our observations, but the possibility that the known superluminally expanding sources are highly symmetric is excluded by VLBI^{15–18}. For example, Shaffer *et al.*¹⁵ found that the two

Fig. 3 As Fig. 1 but for 3C345.

components of 3C345 differed by more than 10% in total flux density and that one component had $B_{\perp} \sim 1$ mG where the other had $B_{\perp} \sim 100$ mG.

The conflict between the model and the observations can be reduced if both source components are opaque to the observer. The degree of circular polarisation from an opaque synchrotron source is about one-third as much as from a transparent source¹⁹. However, unless the observer is in the equatorial plane of the dipole, the two components will become transparent at different times (because of the different distances of the emitting regions from the dipole centre), thus producing a large imbalance between the components some time during the development of the burst. Our observations (see Figs 1–3) show no evidence for periods of large circular polarisation. Except for the possibility that the radiation from extragalactic sources is generated by both positrons and electrons, the asymmetries observed by VLBI together with our measurements of low degrees of circular polarisation in these sources do not seem to be reconcilable with the magnetic dipole model.

We thank F. T. Haddock, T. V. Seling, G. E. Latimer, and K. G. Holmes for design and maintenance of the equipment, M. F. Aller for helpful discussions and J. E. Ledden for some of the total flux density observations. This research was supported by the NSF.

Tropospheric circulation and interplanetary magnetic sector boundaries followed by MeV proton streams

TRANSITS of some interplanetary magnetic sector boundaries across the Earth were shown by Svestka *et al.*¹ to be followed by streams of protons with energies in the range of a few MeV. These proton boundary transits were associated with a characteristic decrease²⁻⁴ of the vorticity area index (VAI) during Northern Hemisphere winter that was about twice as large as the decrease associated with all the other boundary transits during the same interval. I show here that the MeV proton streams associated by Svestka *et al.*¹ with certain sector boundary transits apparently select boundary transits associated with unusually active conditions in the solar wind. These proton boundary transits were associated with a larger change in tropospheric circulation than were the other boundary transits observed during the same interval of time. New information in the present study of sector boundary transits relating changes in solar wind velocity, density and magnetic field to the resulting terrestrial changes in vorticity area index, geomagnetic activity and cosmic ray flux at Earth may provide a test for proposed physical mechanisms.

Svestka *et al.*¹ summarised what they observed: "There are certain magnetic sectors in interplanetary space in which the density of low-energy protons is increased. The increased proton flux is first observed when the western boundary of the sector passes across the Earth. After that time the flux remains enhanced for two or more days. In some cases the duration of the enhancement corresponds to the width of the magnetic sector, but generally this is not the rule; the duration is usually shorter, but it can be even longer than the sector width. In some cases the enhancement is observed once again when the sector returns to Earth after 27 days. More often, however, the proton increase is not recurrent."

Table 1 of Svestka *et al.*¹ gives a list of the transits of magnetic sector boundaries associated with MEV proton streams. The overlap in time between this table and the interval studied in refs 2-4 includes the winters in 1963-69 during which there were 18 proton boundary transits. During the same winter months there were 62 other well defined boundary transits tabulated by Svalgaard^{5,6}.

Figure 1a shows a superposed epoch analysis of the classical VAI of Roberts and Olson⁷ computed at 500 mb in the Northern Hemisphere for the 18 proton boundary transits described above (solid line) and for the 62 other boundary transits in the same interval of time (dashed line). The proton boundary transits were associated with a narrower minimum that was about twice as deep as the minimum associated with the other boundary transits.

Fig. 1 a, Superposed epoch of the vorticity area index during Northern Hemisphere winters 1963-69 about sector boundary transits. The solid curve represents MeV proton boundary transits (see text) and the dashed line represents all other boundary transits in the same time interval. The VAI was computed at 500 mb as the sum of the area in which vorticity was greater than or equal to $20 \times 10^{-5} \text{ s}^{-1}$ plus the area in which vorticity was $\geq 24 \times 10^{-5} \text{ s}^{-1}$. In all figures the error bars indicate $\pm \text{s.e.m.}$ b, The same as (a) except that the vorticity area index was computed at 300 mb for the area in which vorticity was $\geq 28 \times 10^{-5} \text{ s}^{-1}$. Note that the ordinate in (b) is about 10 times smaller than that in (a).

As the depth of the minimum in the VAI may depend on the number of boundary transits considered, an analysis was made using 1,000 groups of 18 boundary transit times selected at random from the 62 'other' transits. A quantitative measure of the depth D of the minimum is defined as the average VAI at day -2 and at day 4 minus the VAI at day 1. (This definition is based on the minimum observed from 162 transits during the winters from 1 November 1963 to 31 March 1976.) For each of the 1,000 groups of 18 transit times the value of D is computed. For the 1,000 values of D the mean is $3.54 (\times 10^5 \text{ km}^2)$ and the standard deviation is 2.04. For the solid curve in Fig. 1a the value of D is 7.32, which is almost two standard deviations larger than the mean. This is consistent with the fact that only 30 (3%) of the 1,000 random values of D were larger than 7.32.

Figure 1b is the same as Fig. 1a except that the VAI was computed in a different part of the troposphere, namely at a height of 300 mb for vorticities $\geq 28 \times 10^{-5} \text{ s}^{-1}$. The VAI in Fig. 1a was computed at 500 mb for vorticities $\geq 20 \times 10^{-5} \text{ s}^{-1}$ plus the area with vorticity $\geq 24 \times 10^{-5} \text{ s}^{-1}$. Note that the area of the troposphere computed in Fig. 1b is about 10 times smaller than in Fig. 1a, but in Fig. 1b the minimum associated with MeV proton boundary transits is again at least twice as deep as the minimum associated with the other boundaries. A very similar effect was thus observed in rather different conditions in the troposphere.

Figure 2 shows a superposed epoch analysis of geomagnetic activity (Mudryaud's index⁸ am) associated with the proton boundary transits (solid line) and the other boundary transits (dashed line). There was a large increase of geomagnetic activity following the proton boundary transits and no significant change

following the other boundary transits. Figure 3 shows a superposed epoch analysis of the magnitude of the observed interplanetary magnetic field associated with proton boundary transits (solid line) and the other boundary transits (dashed line). The field magnitude showed a large increase after the transit of the proton boundaries and no significant change associated with the transit of the other boundaries. The shapes of Figs 2 and 3 are very similar, as would be expected from earlier discussions of the response of geomagnetic activity on this time scale to the solar wind and interplanetary magnetic field⁹. A measure of the information content in the present analysis can be gained from the close similarity of the peaks in the solid lines of Figs 2 and 3.

The MeV proton streams discussed by Svestka *et al.*¹ are now thought to have been accelerated in the solar wind beyond 1 AU in co-rotating interaction regions¹⁰ that are formed when high-velocity solar wind streams are catching up with lower velocity solar wind. The MeV proton boundary transits were thus associated with unusually active solar wind conditions.

Some information about possible physical mechanisms may be inferred from the analysis reported here. The magnitude of the interplanetary magnetic field had a large increase after proton boundary transits and no significant change after the

Fig. 2 Superposed epoch analysis of geomagnetic activity associated with the transit of proton sector boundaries (solid line) and the other boundaries in the same time interval (dashed line).

other boundary transits, while the minimum in VAI after proton boundary transits was twice as deep as the minimum after the other boundary transits. But the minimum in VAI after the other boundary transits was still well-defined. Thus, a simple relationship between the increase in the magnitude of the interplanetary magnetic field and the decrease in VAI following boundary transits seems to be excluded.

Geomagnetic activity had a large increase following proton boundary transits and no significant change associated with the other boundary transits, while the minimum in VAI following proton boundary transits and following the other boundary transits was well defined. We may infer that an increased in geomagnetic activity following a boundary transit is not a necessary condition for a minimum in VAI following a boundary transit. Olsen *et al.*¹¹ have reported a relationship between minimum VAI and maximum geomagnetic activity, but the large increases in geomagnetic activity studied by Olson *et al.*¹¹ were associated with transient solar flares (and/or plagues¹²) while the smaller increases in geomagnetic activity discussed in the present paper were associated with the quasi-stationary

Fig. 3 Superposed epoch analysis of the magnitude of the interplanetary magnetic field associated with the transit of proton boundaries (solid line) and all other boundaries in the same interval (dashed line). Note the similarity between Figs 2 and 3.

co-rotating solar and interplanetary magnetic sector structure¹³. Physical processes may be different in these two cases.

The streams of MeV protons used by Svestka *et al.*¹ to select the proton boundaries analysed in the present work are not necessarily involved in the physical cause of the decrease of VAI following boundary transits. The proton streams may simply mark the presence of unusually disturbed solar wind conditions. Superposed epoch analysis (not shown) of solar wind velocity and of the density showed the characteristic increase¹³ in these quantities following proton boundary transits and following the other boundary transits, but the maximum values were larger after the proton boundary transits than after the other boundary transits. Thus, the increase in solar wind velocity and/or density that followed boundary transits may have been associated with the minima in VAI that followed boundary transits. The galactic cosmic ray intensity observed at Earth (Deep River neutron monitor) decreased by about 1% after the proton boundary transits and did not have a significant variation associated with the other boundary transits. Thus, a decrease in galactic cosmic ray intensity following boundary transits does not seem to be a necessary condition for a decrease in VAI following boundary transits.

Effect of humidity on monolayer desorption at the air-water interface

THE effect of atmospheric humidity on the physicochemical properties of lipid monomolecular films at the air-water interface has been thought to be of secondary importance, and has never been studied experimentally. Yet, the physical situation encountered at the air-water interface may be strongly dependent on the humidity in the gas phase^{1,2}. Harkins³, while not specifically investigating this effect, took painstaking measures to ensure saturation of the air above the interface in an effort to suppress any temperature difference between the interior of the aqueous phase and its free surface. Obviously, below the saturation point of the air, the free surface of water is expected to be at a lower temperature than the interior by virtue of the evaporation of liquid. Thus, in some instances, the temperature of the outermost layer of the free water surface was reported to drop by 15°C or more relative to the temperature of the bulk from measurements of the surface tension during evaporation⁴. In other investigations the mean temperature, measured by thermistors, of a thin region immediately below the free surface of a water pool was reported to be several degrees lower than that in the interior during evaporation¹. The data presented here constitute a clear indication of the decisive effect of atmospheric humidity on the kinetics of monolayer desorption from the air-water interface. Figure 1 illustrates the dramatic difference in the observed decrease of the surface pressure of myristic acid monolayers in three different conditions of atmospheric humidity.

Unstable density and temperature gradients may thus be expected along the depth of a water layer undergoing evaporation. The main effect of these gradients is the generation, at a critical value, of the well known convective flows^{5,6} in which liquid at the surface is driven, by buoyancy or surface tension effects, to the interior and replaced by liquid from below. The intensity of these hydrodynamic effects obviously should be a function of the rate of evaporation (or heat flux) and hence, in the case of water pools, of the relative humidity of the air above

the free liquid surface. As the motion of fluid involves exchange of surface liquid for bulk liquid it could, in principle, affect studies of the dynamics of surfactant molecules both along the interface, such as surface diffusion, or across the interface, such as adsorption-desorption phenomena.

The apparatus used in this study consisted of a 1.6-mm deep Teflon trough, a Wilhelmy-type film balance, three thermistor probes for scanning the temperature of both the liquid and gas phases, and small relative humidity probes placed 5 mm above the interface. The entire system was enclosed in a Lucite cabinet, and the experiments were conducted in a controlled environment room. The cabinet was fitted with small pluggable access ports which served two purposes: first, to allow spreading of the monolayer from *n*-hexane through long capillary tubes, thus minimising disturbances of the physical conditions of the system, and second, to allow for adjustment of the humidity levels in the cabinet which also contained moist filter paper. In every instance spreading of the monolayer was accomplished only after complete stabilisation of the temperature and relative humidity. Every effort was made to check for and eliminate experimental artefacts due to film leakage, contact angle hysteresis, and solvent effects.

It is believed that curve *a* in Fig. 1 represents the rate of monolayer desorption in a convection-free aqueous layer (pH 2.0). The increase in the apparent desorption rate at 68% relative humidity (curve *b*) is presumably due to the convective motion in the liquid which causes a more rapid depletion of surfactant molecules from the surface, perhaps even during the spreading process. Interestingly, if the relative humidity is allowed to increase from 72 to 84% (curve *c*), the apparent film pressure first decreases rapidly, due to enhanced surfactant depletion by convection, and then increases gradually as a result of surfactant readorption which could be aided by the well known suppression of convective motion in liquids by the presence of solvent-free monolayers at the surface. The behaviour depicted also was found to persist for lauric acid monolayers in the liquid-expanded state and, except for curve (*c*), the results for a given surfactant were independent of trough dimensions or construction material.

Ice elevation map of Queen Maud Land, Antarctica, from balloon altimetry

THE technique and expected coverage of ice elevation mapping using radio altimetry data from the Twerle balloons¹, have already been discussed². We present here preliminary results obtained after analysing 18 balloon traverses, with 1,900 elevation points. A map of the entire continent agrees very well

with existing maps, suggesting the validity of the method. A larger-scale, more detailed map of Queen Maud Land permits better delineation of the drainage systems of that region than has previously been possible.

In Fig. 1 the entire continent is separated into 30×38 km rectangles. The digit printed in the rectangle is the 100-m digit of the unweighted average of all elevation readings obtained in that rectangle (S represents the elevation range of 20–99 m). Contour lines at 500-m intervals are plotted where data coverage permits. Figure 2 is an expanded scale of the 330° – 90° E section, with the balloon trajectories and contour lines every 100 m.

The contour lines on both maps are based on the balloon altimetry data alone. The elevation accuracy, has been shown² to be better than 60 m. The data gathered thus far does indicate a change in that figure of accuracy.

Although the map of the entire continent (Fig. 1) does not show any new features of the general pattern of elevations on the Antarctic ice sheet it does demonstrate the validity of the balloon technique by its close correspondence with standard American and Soviet maps of surface elevation of the Antarctic ice sheet based on data from ground traverses and aircraft flights^{3,4}. An example is the occurrence in central East Antarctica of a closed 4,000 m contour similar in size and shape to that previously observed from Soviet over-snow traverses, showing the good agreement between the data from different sources in this region of maximum elevation above sea level and maximum distance from the coast.

The more detailed map (Fig. 2) is of particular interest from the glaciological standpoint, as Queen Maud Land is a region in which there were very few previous elevation data. Although mapping is not yet complete, there are already some interesting features.

For example, a 3,700-m closed contour appears at about 77° S 40° E, indicating a fourth 'dome' along the central East Antarctic Ridge ('Dome A', 'Dome C', to the east, are already well-known). This feature does not appear on either of the standard Antarctic maps^{3,4}, although it is on a map drawn from the measurements on the Japanese traverse in 1968–69 from Syowa to Plateau Station⁵. The contour in Fig. 2 has been shaped to agree with the Japanese map. However, an additional balloon traverse, only partially analysed, hints that this 3,700 m contour is considerably broader, and may extend as far as 34° E.

On the other hand, the absence of a major dome (higher than the contour interval) centred at about 75° S 12° E, that is shown on the American map³ but not on the Soviet map⁴, is confirmed by the present map. Previous data spacing was wide enough to permit either interpretation.

Of more interest than the absence or presence of domes along the summit ridge may be the indication of valleys inland from several coastal glaciers, showing the convergence of ice flow from substantial drainage basins into those glaciers, and in some cases suggesting the occurrence of ice streams. One such valley, presumably feeding into Recovery Glacier, shows clearly around 81° – 82° S, 0° – 10° W, some 350 km inland. Crevasses as

Fig. 1 Elevation map (polar azimuthal equidistance projection) for the whole Antarctic continent from balloon altimeter data. Small numbers denote the hundreds digit in the elevation figure. Contour interval is 500 m.

Fig. 2 Elevation map (polar azimuthal equidistance projection) of Queen Maud Land and neighbouring regions. Thin lines are individual balloon tracks. Contour interval is 100 m.

far inland as $83^{\circ}\text{S } 15^{\circ}\text{E}$ (ref. 6) suggest a deeply penetrating ice stream⁷.

Another valley can be seen around $77.5^{\circ}\text{S } 10^{\circ}\text{W}$. Contour lines have been interpolated between rather widely-spaced balloon tracks on the assumption that this valley is associated with Slessor Glacier. Although that is not definite, the shape of the Coats Land coast necessitates the pronounced westward bowing of the contours north-east of Slessor Glacier (Fig. 2) unless the ice sheet profile in that region is most exceptionally flat. Furthermore, massive outflow through the Recovery Glacier-Slessor Glacier system is consistent with the high movement rates of the Filchner Ice Shelf front around 40°W ⁸. As drawn, this drainage system is the largest in East Antarctica, exceeding that feeding the Amery Ice Shelf by ~20%.

Stancomb-Wills Glacier (Dalgicah Ice Stream) is very fast-moving—the ice shelf it feeds is advancing at almost 1.5 km yr^{-1} (ref. 10). In the light of this, the drainage area that seems to feed it is surprisingly small.

A clear indentation of contours, reflecting a major region of outflow through the mountains of New Schwabenland by Jutulstraumen⁹ appears just north-east of $75^{\circ}\text{S } 0^{\circ}\text{E}$. This valley shows good agreement with elevations from the single traverse line in the region, that of the Norwegian-British-Swedish Antarctic Expedition, 1949–52.

In contrast, there appears from fairly good coverage to be little contour line indentation inland of the Pensacola Mountains, where one might otherwise suspect concentrated drainage through either Support Force Glacier, or Foundation Ice Stream, or both. The total area of the drainage basin feeding the southern Filchner Ice Shelf, formerly thought to be the main source of the ice shelf input¹¹, is now seen to be only about half as large as the Recovery Glacier-Slessor Glacier system.

Work on the mapping of the Antarctic ice sheet from the

balloon data continues, and several of the more speculative features mentioned here clearly require closer examination as the data coverage increases. Nevertheless, the map presented here for Queen Maud Land is already substantially more detailed than any previously available.

The information on which this report is based was obtained during the Tropical Wind, Energy Conversion and Reference Level Experiment (Twerle), supported by NASA and NSF. The analysis is supported by a grant from the US-Israel Binational Science Foundation (BSF), Jerusalem, Israel.

Depth of curie temperature in continental shields: a compositional boundary?

MUCH attention is being given to estimating the depth to the bottom of the crustal magnetised layer. The latter can be interpreted as the surface where ferrimagnetic minerals, which are responsible for the magnetisation of crustal rocks, reach their Curie temperatures ~ 1.5 . The depth of this surface is therefore temperature dependent and it can be used to locate thermal anomalies within the continental crust. One application would be in the search for shallow intercrustal heat sources (such as large magmatic reservoirs or cooling plutons) which would be of economic interest as natural energy sources^{3,6}. In all these works the bottom of the crustal magnetised layer is assumed to correspond to an isotherm whose temperature is approximately the Curie temperature of pure magnetite (580 °C). Haggerty⁷ cautioned against assuming a single Curie temperature for the continental crust and pointed out that Curie temperatures as low as 300 °C may exist in the crust because of the low temperature-oxidation of titaniferous magnetite. Furthermore, he suggested that depths of Curie temperatures greater than 20 km may be due to serpentinisation of mafic and ultramafic components of the continental lower crust with consequent formation of Fe-Co-Ni alloys with Curie temperatures in the range 620–1,100 °C. We show here that depths of Curie temperatures computed for continental areas characterised by normal and low heat flow cannot be interpreted as isothermal surfaces with temperatures at or above 580 °C. We suggest that the bottom of the crustal magnetised layer may correspond to vertical compositional changes within the crust.

This idea occurred to us while we were interpreting the results of the computation of the depth to the bottom of the crustal magnetised layer in southeastern Minas Gerais, Brazil⁸. This is a Precambrian area where extensive outcrops of high grade metamorphic rocks occur. This metamorphic basement was formed 2,000–2,600 Myr ago⁹ and it is locally covered by metasediments of Upper Precambrian age and sediments formed during the last orogenic event which affected this area, the Brazilian orogenesis (600–650 Myr)^{9,10}. A crustal model was computed for a part of this area from gravity data¹¹ also using the information obtained from an unreversed deep refraction profile¹². This model indicates a normal crustal thickness of

Fig. 1 Power spectrum of the total intensity anomaly field in southeastern Minas Gerais, Brazil. Continuous lines are regression lines relative to depth of anomalies at 25–30 km and 2–3 km, respectively.

Fig. 2 Saturation magnetisation plotted against temperatures for two acidic charnockites outcropping along the coast of Sao Paulo State, Brazil. Chemical and petrological data about these rocks are available²⁰. Measurements were carried out on the Curie balance of the Istituto di Geologia e Geofisica of the University of Napoli, Italy²⁷. O, MP003; □, MP035.

38–40 km with local thickening to 45 km (see Fig. 3). Furthermore, predominantly acidic rocks seem to be the crustal constituents at least to a depth of 22–25 km. The gravity derived model requires a lower crustal layer with density between 2.8 and 3.3 g cm⁻³. If a density of 3.0 g cm⁻³ is assumed, the normal depth to the top of this layer is about 23–22 km, with local thickening to 25 km. Seismic data¹² indicate a continuous increase of P-wave velocities in the lowermost 15 km of crust, with an average velocity of 7.4 km s⁻¹. Preliminary heat flow data in this area are in the range of 40–50 mW m⁻² with temperature gradients in the range 10–16 °C km⁻¹ (ref. 13).

The depth to the bottom of the magnetized crustal layer was computed from a very detailed aeromagnetic survey which was carried out in 1973 by the German company Prakla and the Brazilian Companhia de Pesquisa de Recursos Minerais¹⁴. The map of the total intensity anomalies was averaged on a 10 × 10 km grid and was then submitted to Fourier analysis. A typical power spectrum is given in Fig. 1. The decay of the energy content with frequency¹⁵ indicates a distribution of anomaly sources at 25–30 km at a depth of 2–3 km. A low pass filter with cut-off at 0.013 cycles per km (wavelength 80 km) was applied. The resultant residual anomalies were inverted by using two-dimensional polygonal bodies of uniform magnetisation whose upper surface corresponds to the ground level and the depth and morphology of its bottom is computed by iterative procedures which compare the theoretical field produced by the model with the observed field. The computed depths are in the range 22–27 km⁸.

These depths are in the range of 'normal' depths reported in the literature for areas of normal and slightly higher than normal heat flow^{4,5}. The average depth of Curie temperature in continental areas was estimated to be about 20 km (ref. 1). A linear extrapolation of shallow temperature gradients would actually predict temperatures higher than 500 °C at a depth of 20 km in areas of normal heat flow. However, a constant temperature gradient within the continental crust is not allowed by the energy balance between the measured heat flow and the radiogenic heat production determined on rocks which are believed to be the main constituents of the upper continental crust. Heat flows and radiogenic heat productions measured in

continental areas require a strong depletion of radioactive elements with depth¹⁶⁻¹⁸. This is also supported by geochemical considerations¹⁹. The main consequence of an upward concentration of radioactive elements is that the temperature gradient decreases with depth. Figure 3 shows the highest temperatures which can be reached within the crust of a normal heat flow area¹⁷. This temperature profile was calculated by assuming a stepwise distribution of radioactive elements, that is, a 5-km thick upper crustal layer with concentrations typical of acidic intrusive rocks and a 35-km layer with concentrations typical of high grade metamorphic rocks¹⁷. The highest temperatures which can be reached at 20–25 km of depth are about 250–300 °C. Temperatures above 500 °C can be reached only below the crust–upper mantle boundary. Only in areas with heat flow higher than 80 mW.m⁻², temperatures of 500–580 °C are possible at a depth of about 20 km. Different models of depletion of radioactive elements with depth do not significantly change these conclusions^{18,20}. Therefore the bottom of the crustal magnetised layer computed for areas of normal and low heat flow cannot represent an isothermal surface at 500–580 °C.

Geophysical models of the continental crust of typical Precambrian areas, such as the Canadian Shield²¹ or the Baltic Shield²², are similar to that inferred for Minas Gerais (Fig. 3). P-wave velocities of 6.1–6.3 km.s⁻¹ and densities of 2.8–2.9 g.cm⁻³ are determined down to a depth of 15–20 km. These characteristics are consistent with the occurrence of rocks of acidic composition and low to high (granulite facies) metamorphic grade²³. P-wave velocities of 6.8–7.4 km.s⁻¹ and density ~3.0 g cm⁻³ are usually inferred for the lower continental crust. Some geophysicists²⁴ believe that higher seismic velocities and densities of the deep continental crust are due to a progressive increase of metamorphic grade. However, P-wave velocities higher than 6.8 km.s⁻¹ have been measured in granulitic facies rocks with at least 40% pyroxene plus hornblende at pressures of 4–10 kbar²⁵. Although the available seismic data indicate a very complex structure for the continental lower crust²⁵, the increase of metamorphic grade must be accompanied by a change of chemical composition toward intermediate or mafic in order to fit the seismic velocities²³.

Curie temperatures of acidic rocks are unlikely to be lower than 500 °C. It is well known that plutonic rocks and lavas of acidic composition contain almost pure magnetite as the main ferrimagnetic phase²⁶. Curie temperatures above 500 °C have also been measured in acidic rocks which are stable in the lower continental crust. Saturation magnetisation versus temperature curves for two charnockites outcropping along the coast of São Paulo State, Brazil, are reported in Fig. 2. One curve has a clear Curie temperature at 580 °C, indicating that pure magnetite is the main ferrimagnetic phase. The other sample is characterised by a more complex curve, with a tail to about 700 °C. This is probably a consequence of low temperature oxidation of the rock with resulting production of maghemite (Curie temperature 545 °C), which, being unstable at temperatures between 250

and 550 °C, tends to transform into hematite (Curie temperature 860 °C). High grade metamorphism of acidic rocks is hence unlikely to give rise to low Curie temperature ferrimagnetic phases.

Ferrimagnetic phases contained in alkali-basaltic and andesitic rocks are intermediate members of the ulvöspinel-magnetite solid solution series, with Curie temperatures in the range 100–300 °C^{26,27}. No experimental data are available on Curie temperatures of high grade metamorphic rocks of intermediate to mafic composition. However, in this case magnetisation of the intermediate members of the ulvöspinel-magnetite solid solution series would produce Curie temperatures in the range 300–450 °C⁷. Curie temperatures of rocks of intermediate (andesitic) or mafic composition are in the range of possible crustal temperatures of Precambrian areas. The Curie temperature at depth can therefore correspond to the surface where a change of chemical composition of crustal rocks occurs.

Figure 3 shows this correspondence with reference to the crustal model of southeastern Minas Gerais, Brazil. The Curie temperature is assumed to be 580 °C in the upper crust and about 200 °C in the lower crust. The bottom of the magnetised layer (dashed area) is slightly below the top of the lower crustal layer and corresponds to a compositional change of the crust towards more mafic terms.

If this interpretation is correct, the depth of Curie temperature is not sensitive to small variations in the thermal state of the crust, but only to the composition of rocks at that depth. The depth of Curie temperature can be used therefore as a marker of vertical changes in chemical composition of the continental crust in normal heat flow areas.

We thank Dr M. H. Teixeira Mendes and C. C. de Sá for the aeromagnetic data, and Dr R. Scandone for technical help. This research was partially carried out when P.G. was visiting professor at IAG-USP with a grant from FAPESP No. 77/0899.

Palaeo-oceanography of the post-glacial Eastern Mediterranean

DURING the late Pleistocene the hydrography of the Eastern Mediterranean underwent severe changes in response to climatic fluctuations. Among the most striking of these changes were periods of deep water stagnation. Episodes of oxygen depletion are indicated by the presence of layers of dark sapropelic muds enriched in organic carbon, devoid of the remains of benthic organisms¹⁻⁴. While stagnant conditions prevailed in the deep basin, the water column above 1,000–800 m remained ventilated, and cores raised above this depth do not contain sapropels⁴⁻⁶. Several theories have been proposed to explain the past stagnations. They all use a mechanism which stabilises the water column by forming a steep density gradient in the upper waters. In this way the vertical mixing, and hence the ventilation, are retarded, oxygen is depleted in the deep water and stagnation commences. Olauson's theory⁷, whereby influx of freshwater leads to reduced surface density and the interruption of normal vertical circulation, is the most widely accepted at present. This theory is supported by recent studies⁸⁻¹⁰, which use measurements of oxygen isotope composition in shells of planktonic foraminifera. These studies demonstrate that many of the sapropels correspond to $\delta^{18}\text{O}$ minima, suggesting freshwater influx, and thus a reduced upper water salinity at the time of the sapropel formation. Moreover, the epipelagic species record greater depletion of ^{18}O than the mesopelagic species, indicative of the establishment of salinity and density gradient in the upper waters¹⁰. Using a similar approach we have attempted to investigate in detail the hydrographic changes associated with the deposition of the most recent sapropel, which took place about 7,000–9,000 yr BP⁶.

Core GA32 from the continental slope off Israel—an area of very rapid accumulation of Nile derived sediments¹¹⁻¹³—was sampled every 10 cm, which represent intervals of about 300 yr. The epipelagic planktonic species *Globigerinoides ruber* and the benthonic species *Uvigerina mediterranea* were chosen for analyses of $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$. Being a shallow core, GA32 does not contain any sapropels. However, determination of the core interval corresponding to the time of the last sapropel deposition in the deep cores is straightforward when the $\delta^{18}\text{O}$ minimum of *G. ruber* (230–320 cm, Fig. 1) is used to correlate other core records such as RC9–181 and TR172–22^{8,9}. A time scale based on this correlation and on an assumption of constant accumulation rate is used in Fig. 1. Note that this scale should be used only as a rough guide because the accumulation rate of the core might not be uniform¹².

In general the benthonic species is enriched in ^{18}O relative to the planktonic species. At present this difference is primarily due to two effects. The oxygen isotopic fractionation between the calcitic shells and the seawater is temperature dependent, therefore at 590 m ($\sim 14^\circ\text{C}$) ^{18}O becomes more enriched in the shells than at the surface ($18\text{--}28^\circ\text{C}$). In addition, nonequilibrium isotopic fractionation due to vital effects¹⁴⁻¹⁶ would tend to increase the difference between *G. ruber* and *U. mediterranea*.

Assuming that *G. ruber* has not undergone significant environmental adjustments such as a change in its depth habitat or a change in the season of optimal shell production, and that the isotopic fractionation between the shells of both species and the seawater has remained nearly constant during the past 12,000 yr, hydrographic conditions can be inferred from the isotopic variations.

Rapid ^{18}O depletion in both the planktonic and the benthonic species is registered in the lower part of GA32. This depletion corresponds to a transition from cool to warmer faunal composition in the area which was attributed to the ending of the last Glacial^{12,17}. Nevertheless, it seems that temperature alone would not account for all the isotopic change, as the faunal change over the same period is small, and temperature estimates

based on this change suggest that the temperature rise did not exceed $2\text{--}3^\circ\text{C}$ ⁹. Thus the major part of the isotopic change ($\sim 1.5\%$) has to be accounted for by an influx of freshwater. It has been suggested that glacier melt-water was the major source of this influx¹⁰, but increased precipitation at about the same time cannot be neglected⁹. In either case, the freshwater input would result in a considerable reduction of the surface salinity ($2\text{--}3\%$)¹⁰.

It is significant that the salinity changes on the bottom lag behind the surface changes. This lag is explained by a very slow mixing of the low salinity surface layer. For $\sim 1,500$ yr there was enough freshwater input to cope with the vertical mixing, and throughout this period stable stratification of the upper water column was maintained, as is evident from the difference between the isotopic composition of the surface dwelling and bottom dwelling foraminifera (Fig. 1). Following a brief reduction in the steepness of the density gradient ($\sim 7,500$ yr BP), stable water-mass stratification was re-established for several hundred years. It seems then that the supply of freshwater was not steady throughout the deposition of the last sapropel. Further indication of this is found in cores from the Adriatic Sea, and also in some deep cores from the Levantine basin, where the last sapropel is interrupted by a short period of ventilated bottom water^{4,8}. However, in many deep cores from the Eastern Mediterranean there is no such interruption. This might indicate that only part of the basin was ventilated in this short period, or that the rate of accumulation of many cores is too slow and a short event cannot be recorded.

Following the sapropel time, the $\delta^{18}\text{O}$ curves register only small fluctuations, and thus indicate relatively stable climatic and hydrographic conditions. However, in the period 4,000–3,000 yr BP the planktonic species was enriched in ^{18}O , and the difference between the lower and upper waters is reduced. This might indicate a more arid climate during this period.

Unlike the $\delta^{18}\text{O}$ in the foraminiferal shells, the $\delta^{13}\text{C}$ is not directly influenced by changes in the evaporation-precipitation budget, and its temperature dependence is small. Rather, it depends mainly on the isotopic composition of the dissolved CO_2 in the seawater, and on some biogenic effects which influence the isotopic fractionation^{15,16,18,19}.

The $\delta^{13}\text{C}$ in *G. ruber* from GA32 is 1.4% on the average and

Fig. 1 $\delta^{18}\text{O}$ curves of the benthonic (B) species *Uvigerina mediterranea*, the planktonic (P) species *Globigerinoides ruber*, the difference ($\Delta\delta^{18}\text{O}$) between the planktonic and the benthonic species, and $\delta^{13}\text{C}$ curve of the benthonic species. Standard procedures were followed in the isotopic analyses²³, and 20 specimens of the planktonic species and five specimens of the benthonic were analysed on a Micromass 602C mass-spectrometer. Conversion to PDB was done through the CalTech standard PDB IV.

varies by about $\pm 0.5\%$. However, its changing values do not show an understandable trend. In this respect the record of GA32 is no exception to other such records of planktonic foraminifera from the Eastern Mediterranean^{9,20}. The $\delta^{13}\text{C}$ curve obtained for the benthonic species in turn shows a distinct minimum centred around 7,000 yr BP. This minimum probably resulted from increased proportion of dissolved carbon dioxide which originated from oxidation of organic matter. A similar process leads today to the formation of the $\delta^{13}\text{C}$ minimum which is closely associated with the oceanic oxygen minimum layer^{20,22}. Thus during periods of oxygen depletion in the deep parts of the Eastern Mediterranean basin, the $\delta^{13}\text{C}$ of the dissolved CO_2 decreased. The layer of the low oxygen content and low $\delta^{13}\text{C}$ propagated slowly upwards, and thus the minimum values reached the depth of a few hundred metres only 1,500 yr after the initiation of increased freshwater influx. Once this influx decreased and the ventilation resumed, the carbon isotope composition returned back to the pre-sapropel values. It is also possible that the ^{13}C -depleted carbon dioxide was not derived from direct oxidation of organic matter in the water column, but from oxidation of organic remains in the sediment. The latter process is slower, and might explain the slow response of the $\delta^{13}\text{C}$ to the changes in surface conditions.

Evidence against Fisher's theory of dominance

FISHER'S theory of the evolution of dominance is based on the fact that heterozygotes for rare deleterious alleles, maintained by recurrent mutation from the wild-type allele at the locus, greatly outnumber homozygotes in a random-mating population at equilibrium¹. The fitness of a heterozygote carrying a mutant and the wild-type allele can be written as $1 - hs$ ($1 \gg h \gg 0$), compared with fitnesses of 1 and $1 - s$ for wild-type and mutant homozygotes respectively. Fisher postulated that mutant alleles were originally semidominant, so that $h > 0$. He explained the fact that most mutations are observed to be

recessive or nearly recessive to wild type as the result of selection for modifier genes which increase the fitness of the heterozygotes alone. He pointed out that selection to improve the fitness of the mutant homozygotes is likely to be relatively ineffective because of their rarity compared with the heterozygotes, and also because the presence of the wild-type allele in heterozygotes renders them more amenable to selection towards the wild type. Using this theory, the level of dominance of the mutant alleles, h , is gradually reduced towards zero, while s remains constant. Wright² criticised this because the heterozygotes for mutant alleles are so rare that the intensity of selection on a gene which modifies h is of the same order as the rate of mutation, u , to deleterious alleles at the locus undergoing dominance modification. He suggested that such a weak selection pressure is unlikely to overcome the effects of random genetic drift, or the selective consequences of pleiotropic effects of the dominance modifier. Later theoretical work^{3,4} has confirmed Wright's conclusion about the intensity of selection on dominance modifiers, so that many geneticists have come to doubt the validity of Fisher's theory⁵. The principle of dominance modification when applied to balanced polymorphisms (for example, Batesian mimicry⁶) is not, of course, subject to this objection and is generally accepted. Fisher¹, however, believed that the recessivity of mutant genes demonstrated the ability of even a minute selection pressure to cause significant evolutionary change. The issue cannot be settled by purely theoretical considerations, and it is evident that some empirical evidence capable of providing a critical test is required. (Demonstrations that dominance can be modified by artificial selection^{6,7}, although of great interest, are not relevant to the question of the efficacy of selection pressures as small as those postulated in Fisher's theory.) This paper points out recent experimental evidence on the heterozygous effects of mutations affecting viability in *Drosophila*⁸ that seems to be inconsistent with Fisher's theory, and also looks at two alternative theories proposed by Haldane⁹.

Fisher's theory implies that the intensity of selection on a modifier of dominance depends only on the mutation rate and the extent to which the level of dominance is affected by the modifier, and is independent of the homozygous effect of the mutant alleles^{2,3}. The reason for this can be seen as follows. The increment in fitness to the heterozygote after reducing h by a quantity Δh is $s\Delta h$. But the frequency of the heterozygotes is approximately $2u/hs$ ^{1,2}, so that the net intensity of selection on a modifier with effect Δh is $2u\Delta h/h$, which is independent of s . This argument tacitly assumes that linkage disequilibrium between the modifier and the primary locus can be neglected. Exact numerical computations of population trajectories suggest that this assumption gives an excellent approximation^{3,10}, except when dominance modification has proceeded so far that the mutant alleles have been rendered almost recessive. A similar conclusion about the lack of dependence of the strength of selection for dominance modification on s is true for the two models suggested by Haldane⁹. The first of these involves the selection of wild-type isalleles which are more dominant than the original wild type over the mutant alleles at a locus. The second involves selection for modifiers that strengthen the dominance of a favourable gene which is in the process of replacing an alternative allele. All three models predict that dominance should be reduced at about the same rate for genes with drastic effects on fitness as for genes with minor effects, so that no relationship between h and s should be observable.

The extensive literature on the heterozygous effects of deleterious genes affecting egg-to-adult viability in *Drosophila* was recently reviewed by Simmons and Crow⁸. It seems clear that newly-arisen spontaneous lethal mutations lower viability by 2–4% when heterozygous, giving an average h value of about 0.03 (ref. 11). The evidence is less clear for lethals derived from natural populations. Some studies have suggested heterotic effects of lethals^{12–14}, although most experiments seem to show small, deleterious effects of heterozygous lethals⁸. There is no indication, however, of anything but a small h value, of the order

of a few per cent, so lethals are usually nearly recessive in their effects on viability. This contrasts with findings on mildly deleterious genes. The evidence suggests an average h value of about 0.35 for newly-arisen, spontaneous mutations of small homozygous effect^{15,16}, and about 0.2–0.3 for mildly deleterious mutations carried on chromosomes extracted from natural populations^{8,16}. Although there are some technical problems associated with these estimates^{8,17,18}, the biases are in the direction of underestimating h for mildly deleterious genes. The experimental evidence therefore seems to contradict the predictions of the above models for the evolution of dominance, as h is found to be negatively correlated with s .

In contrast, Wright's² physiological theory of dominance predicts this type of relationship between h and s (ref. 19). This theory assumes that the function of most gene loci is to specify the structure of enzymes, and that most mutations cause a reduction in enzyme activity. If the wild-type enzyme is so active that the concentration of substrate rather than enzyme is rate-limiting for the enzyme-catalysed reaction in wild-type homozygotes, then the rate of the reaction is likely to show a law of diminishing returns as a function of the concentration or activity of the enzyme. This leads to the property that an allele that only slightly reduces enzyme activity is more nearly semi-dominant in combination with a wild-type allele conferring full activity, than an allele which reduces activity to near zero. If there is a relationship between fitness and the rate of production of the end product of the pathway in which the enzyme is involved, alleles with a high s will have a low h , and vice versa¹⁹. This theory requires that the wild-type enzyme has such a high activity that halving the concentration of enzyme produces only a small reduction in the reaction rate². Plunkett²⁰ and Muller²¹ have proposed models in which selection for buffering of the wild-type homozygotes provides an explanation for this apparently unnecessarily high efficiency of the wild-type enzyme.

In summary, the observation that h is negatively correlated with s for viability mutations of *Drosophila* suggests that either dominance of the wild-type allele is a purely biochemical phenomenon and has not been selected for, or that it has evolved by mechanisms other than those suggested by Fisher¹ and Haldane⁹.

Delayed implantation is under environmental control in the badger (*Meles meles* L.)

IN the wild state, the European badger (*Meles meles* L.) becomes pregnant once a year during a post-partum oestrus in February or March¹. Fertilisation is followed, at the blastocyst stage of development, by a prolonged embryonic diapause which ends, when implantation occurs, in December or January. Implantation is thus delayed for 10 months² and it may be assumed, in accordance with Fries's hypothesis³, that the resumption of development in the winter is a genetically determined and adaptive phenomenon which results in birth during the spring when conditions for the young are most favourable. This pattern suggests that the time of implantation is related to some environmental factor such as photoperiod or temperature. To test this hypothesis, wild female badgers were captured in their set after fecundation and maintained during summer in conditions of 'artificial winter'. We report here that in such conditions implantation, gestation and birth can be brought forward 4 months.

Six females were kept at +5 °C in short photoperiod (10 h light: 14 h dark) from July to September. Lighting was provided by fluorescent lamps and the mean intensity of light was about 300 lx. Females were bled once a week and progesterone in plasma was determined, using a radioimmunoassay previously described⁴, to show the changing level of luteal secretion during the period of observation. In natural conditions of daylight and temperature, embryonic diapause in the badger is characterised by a low level of progesterone, the mean not exceeding 6.51 ± 1.60 ng ml⁻¹ (ref. 4). In contrast, just before implantation at the end of December or in January we have found that the level reaches the highest mean value achieved after fertilisation (16.9 ± 2.39 ng ml⁻¹) (ref. 4). When the photoperiod and temperature were decreased experimentally in July, there was a sharp increase in plasma progesterone to peak values (18 ± 0.91 ng ml⁻¹) similarly observed at implantation in January (20.16 ± 1.58 ng ml⁻¹). Experimental females whelped in early September, with plasma progesterone levels during gestation similar to those characterising pregnancy in animals kept in normal conditions of light and temperature (Fig. 1). The litters born in September 1978, that is during the summer, would have

Fig. 1 ●, Progesterone profile during pregnancy in five control badgers (natural daylight and temperature conditions, mean $\pm$ s.e.m.). ○, Progesterone profile in six experimental females subjected to "artificial winter" (mean $\pm$ s.e.m.). With environmental parameters: daylight 10 h, temperature +5 °C unchanged from the beginning of experiment. I, implantation; P, parturition.

been dropped in the following spring had the animals not been exposed to our experimental conditions.

Many mammals undergo well defined annual cycles of sexual activity, and it has been demonstrated in several species that the cycle is influenced by photoperiod^{5,6}. In the mink⁷⁻⁹ and in the marten¹⁰ gestation becomes shorter when the photoperiod is increased artificially.

The experiment described here shows that full luteal function can be stimulated in the badger by manipulating the photoperiod and temperature, and it also suggests that in artificial conditions badgers could have two litters a year. The result conforms with our hypothesis that the hormonal changes which control implantation in the badger are activated by what we have called an 'impulsive factor'¹¹. Further experiments are underway to determine the relative significance of temperature and light in the operation of this factor.

Pattern-selective adaptation in visual cortical neurones

PROLONGED viewing of a grating pattern produces striking 'after-effects', involving changes in the detectability, apparent size, orientation and contrast of subsequently viewed gratings¹⁻³. Studies of perceptual after-effects have been used to infer properties of neurones in the human visual cortex^{2,4,5} similar to those pattern-selective neurones whose sensitivities have been directly measured in the visual cortex of cats and monkeys^{6,7}. Such inferences are based on two assumptions: first, that perceptual changes result from changes in the distribution of activity within the responding population of neurones; second, that the effect of adaptation on each neurone of the population is to reduce its sensitivity uniformly to all stimuli. The experimental results reported here support the first but challenge the second assumption, as they show that after adaptation to a particular grating the sensitivity of a single neurone to that grating may be reduced more than its sensitivity to other gratings.

We recorded the activity of single neurones in the portion of the striate cortex representing the central visual field in young adult cats anaesthetised with nitrous oxide, using methods described in detail elsewhere⁸. The after-effects of prolonged stimulation by grating patterns were examined in 20 cells in five cats. Initially, we explored the receptive fields of each neurone with bars, edges and spots, and as a result classified them as simple, complex or hypercomplex^{6,7}. The face of a display

Fig. 1 Responses of a simple cell to gratings of different contrast, obtained before (a), during (b) and after (c) a period of adaptation. a Shows averaged responses to gratings of 0.75 c deg^{-1} , moving at 2 Hz in the optimal direction, presented at the five contrasts indicated on the right. Each grating was presented 20 times, each time for two stimulus cycles; each histogram thus shows the response to the passage of two bars of the grating across the receptive field. b Shows the responses to the test stimuli while the neurone was fully adapted to the same grating presented at high contrast (0.71). Each test stimulus was preceded by a presentation of the adapting stimulus. c Shows responses to the same test stimuli, measured in an experiment begun 12 min after the end of the adaptation experiment.

oscilloscope, which subtended a circle 10° in diameter at the cat's eye, was then centred on the receptive field (in the dominant eye); the other eye was covered.

The luminance of the oscilloscope screen (which was kept at a space average of 6 cd m^{-2} throughout) could be spatially modulated by signals from a computer to produce sinusoidal gratings. These are patterns of light and dark bars whose luminance profile perpendicular to the bars is a sine wave; their spatial frequency is the number of cycles that subtend one degree of visual angle, and their contrast is the difference between the maximum and minimum luminance divided by twice the mean luminance. All the gratings moved steadily in a direction orthogonal to their bars at 2 Hz (so that two cycles crossed any point on the screen in 1 s). The computer controlled the orientation, direction of movement, spatial frequency and contrast of the grating, and also, within the limits of the 10° field, its spatial extent. While presenting grating patterns, the computer counted action potentials and compiled them into average response histograms; these were saved on disk for later analysis.

For each neurone we first established the spatial frequency, orientation, extent and direction of movement of the optimal grating; then, using optimal stimuli, we measured the relationship between response and stimulus contrast. Figure 1a shows the results of a set of such measurements. In this and all other experiments, the stimuli were presented in blocks. Within a block, each stimulus was presented once for 1 s, during which two cycles of the grating crossed the receptive field. The order of presentation within a block was random and different within each block, of which there were normally 20 in an experiment.

The contrast-response relationship was then determined again, while the neurone was fully adapted to a high-contrast grating. Each block of this 'adaptation' experiment began with a 32- or 64-s presentation of the adapting grating; each test stimulus after the first was preceded by a 4- or 8-s topping-up presentation of the adapting stimulus². Figure 1b shows the results of an experiment in which the adapting stimulus was of optimum spatial frequency and orientation. A comparison of these responses with their counterparts in Fig. 1a shows clearly that prolonged stimulation by a high-contrast grating greatly reduced the strength of responses. In separate experiments we established that the initial period of adaptation used was

sufficient to produce the maximum reduction in sensitivity, and that the topping-up period was sufficient to maintain it.

Figure 1c shows the results of measurements begun 12 min after adaptation, by which time responses had fully recovered. In all cases, except three where the unit was lost, we verified that within 5–15 min after the end of adaptation, responses were similar to those observed before adaptation.

Figure 2A shows the full results of this experiment, which was carried out on a simple cell, and Fig. 2B shows the results of a similar experiment on a complex cell. For both neurones, Fig. 2 shows the contrast-response relationship measured before adaptation (a), while the cell was fully adapted (b) and after a period of recovery (c). For both neurones, adaptation raised the contrast required to produce a given response by a factor of about four, and recovery returned it to very nearly its former value. Although the changes brought about by adaptation are apparently very similar in form for the two units when expressed in this way, the extent to which the response to a grating of fixed contrast is reduced by adaptation may be a poor guide to the extent of this adaptation. Thus, in the case of the complex cell, adaptation produces a much smaller reduction in the response to high-contrast stimuli than it does to ones of lower contrast. Increase in the contrast required to produce a given response (that is, reduction in sensitivity) seems to be the appropriate measure of adaptation.

To ascertain how great a change in sensitivity is brought about by an adapting stimulus, one must compare responses to stimuli of different contrasts presented before, during and after adaptation. Adaptation brought about clear reductions in sensitivity in 19 of the 20 neurones we studied; the remaining unit, a

Fig. 2 The effect of adaptation on contrast-response relations. **A**, Results of the experiment partially illustrated in Fig. 1. **a** Shows the contrast-response relationship measured before adaptation, **b** shows the relationship while the cell was fully adapted, and **c** shows it after a 12-min recovery period. **B**, Results of a similar experiment on a complex cell; the spatial frequency of all gratings was 2.0 c deg^{-1} , and they moved at 2 Hz. Horizontal dashed lines indicate spontaneous activity. As in **A**, the three graphs show measurements made before (**a**), during (**b**) and after (**c**) adaptation. The vertical bar on each graph indicates the contrast necessary to elicit a criterion response of 5 impulses s^{-1} above spontaneous firing. Comparison of these criterion contrasts provides a useful index of adaptation; within limits, the choice of criterion does not strongly affect the index obtained. Here and in Fig. 3, the response plotted is the average discharge rate elicited by the stimulus. This is the natural measure of the response of complex cells, which do not give modulated responses to most gratings; simple cells do give modulated responses but as they generally lack maintained discharge, measures of modulated or unmodulated responses are very well correlated (see Fig. 1).

Fig. 3 The spatial frequency selective nature of adaptation. In these experiments, on a complex cell, test gratings of 0.5 and 1.5 c deg^{-1} were used. **a** Shows the contrast-response relationship for both spatial frequencies, measured before adaptation. **b** Shows the results of an adaptation experiment in which the adapting grating had a contrast of 0.71 and a spatial frequency of 0.5 c deg^{-1} . **c** Shows the results of a similar experiment in which the adapting grating had a contrast of 0.71 and a spatial frequency of 1.5 c deg^{-1} . The vertical bars on each graph, as in Fig. 2, indicate the contrast needed to elicit a criterion response (here, $10 \text{ impulses s}^{-1}$ above spontaneous level). Each adaptation experiment was followed by a period of recovery, during which we verified that responses had returned to pre-adaptation levels. The ratios of the post-adaptation and pre-adaptation contrasts needed to elicit the criterion response are shown on each of the four lower graphs; values greater than 1 indicate an elevation of this 'threshold', values less than 1 a reduction.

monocularly driven neurone with unusually broad orientation selectivity, showed no reliable effects. Spontaneous activity was not always depressed by adaptation.

We were especially interested to know whether the reduction in sensitivity that followed adaptation was confined to stimuli of the same spatial frequency as the adapting pattern; we examined this question in experiments where the spatial frequencies of the test and adapting patterns were varied. The graphs in Fig. 3a show contrast-response relationships for a complex cell, obtained with gratings of 0.5 and 1.5 c deg^{-1} ; vertical bars mark the contrast needed to produce a response of $10 \text{ impulses s}^{-1}$. The graphs in Fig. 3b show the same relationships obtained during adaptation to a grating of 0.5 c deg^{-1} . Responses to gratings of this spatial frequency were much reduced by adaptation (the contrast required to produce a response of $10 \text{ impulses s}^{-1}$ was elevated by a factor of more than three), whereas responses to gratings of 1.5 c deg^{-1} were hardly affected. The graphs in Fig. 3c show the results of a complementary experiment, in which the spatial frequency of the adapting grating was 1.5 c deg^{-1} . In this case, sensitivity for test gratings of 0.5 c deg^{-1} was unaffected, whereas sensitivity for gratings of 1.5 c deg^{-1} was much reduced. The effect of adaptation on this neurone cannot be explained by a uniform change in sensitivity; some spatial frequency selective mechanism must be involved. We observed behaviour of this kind in all seven complex neurones in which we studied the spatial frequency selectivity of adaptation; of three simple cells, one seemed to show spatial frequency selective adaptation, one definitely did not, and the third gave variable results.

Our experiments confirm two earlier reports that the behaviour of cortical neurones may be altered following a period of prolonged stimulation^{9,10}. However, it is necessary to

measure sensitivity in order to characterise the changes adequately; alterations in spontaneous activity, or in responses to high-contrast stimuli, provide an incomplete description of the effects of adaptation.

Our most surprising observation is that the loss of sensitivity in cortical neurones can be specific to the adapting stimulus. Our observations on complex cells might be explained by supposing that each complex cell is excited by a group of simple cells having different frequency selectivities. However, because the spatial frequency selectivity of complex cells is little different from that of simple cells¹¹, and because we have observed frequency-selective adaptation in a simple cell, this is not a convincing argument. Alternatively, adaptation in both simple and complex cells might result from changes in the afferent relay from the lateral geniculate nucleus. Again, this seems unlikely, as the spatial frequency selectivity of cortical neurones is far greater than that of geniculate neurones¹², and also as we have found in separate experiments that the responses of geniculate cells are unaffected by adaptation. We are left with the suggestion that some pattern-selective, perhaps inhibitory, cortical mechanism is involved.

Our observed frequency-selective loss of sensitivity is inconsistent with some models of perceptual after-effects^{2,5}. Although our experiments do not question the idea that human perceptual adaptation reflects adaptation in cortical neurones, they do limit the inferences about the properties of these neurones that may be based on adaptation experiments in man.

Effects of calcium on the intensity-response curve of toad rods

THERE is evidence that Ca^{2+} is stored in the saccules in the outer segments of vertebrate rods, and released by light (for review, see ref. 1). Thus, light apparently increases $[\text{Ca}^{2+}]_i$, the cytoplasmic Ca^{2+} concentration. It now seems unlikely that this increase of $[\text{Ca}^{2+}]_i$ serves as an internal transmitter in generating the light response²⁻⁴. However, there is compelling evidence in the ventral photoreceptors of *Limulus*^{5,6} that it reduces photoreceptor sensitivity during light adaptation. In vertebrate rods an alteration of $[\text{Ca}^{2+}]_o$, the external Ca^{2+} concentration, alters $[\text{Ca}^{2+}]_i$, and the primary effects of changing $[\text{Ca}^{2+}]_o$ seem to be exerted inside the cell^{1,7,8}. Increased $[\text{Ca}^{2+}]_o$ mimics certain aspects of light adaptation, including hyperpolarisation of the resting membrane potential and reduction of light responses⁹⁻¹¹. Light adaptation also shifts the entire

intensity-response function (the V -log I curve) towards higher intensities on the intensity axis, thus reducing the sensitivity of toad rods¹¹. We report here that increased $[\text{Ca}^{2+}]_o$ can mimic this important aspect of light adaptation, whereas lowered $[\text{Ca}^{2+}]_o$ mimics dark adaptation. Control experiments indicate why altered $[\text{Ca}^{2+}]_o$ did not shift the V -log I curve in the recent work of Lipton, Ostroy and Dowling¹¹, who thus concluded that Ca^{2+} does not control this major aspect of photoreceptor sensitivity.

Experiments were carried out in the isolated, inverted and superfused retina of the toad, *Bufo marinus*, as described previously¹⁰. The receptor surface was viewed with a high-resolution infrared imaging system, and only retinal areas were used where the receptors were normal in appearance over a large area. Contact of the electrode tip with the distal end of an outer segment was readily visualised, and most recordings were from outer segments¹⁰. Deeper recordings, some of which were probably from inner segments, gave results similar to those obtained in outer segments. All recordings were from red rods, as determined by maximum sensitivity at about 500 nm. Ultra-fine micropipette electrodes were formed and advanced by previously described techniques¹²; intracellular recordings were readily obtained showing relatively large membrane potentials and light responses that could be maintained stably for up to 3 h. Light stimuli were introduced from below and focused by the condenser system of the microscope. Our control perfusate contained: NaCl (94 mM), KCl (2 mM), MgCl_2 (1 mM), NaHCO_3 (15 mM), glucose (10 mM) and CaCl_2 (1.8 mM). After bubbling with 98.5% O_2 and 1.5% CO_2 , it had a pH of 7.7-7.8; the temperature was maintained at 21-23°C. In this solution both the concentration of bicarbonate and the pH at our maintained temperature were based on an analysis of blood plasma in *Bufo marinus*¹³.

Figure 1 shows fully dark adapted V -log I curves of a single cell at three values of $[\text{Ca}^{2+}]_o$. It is critical to test ionic effects on photoreceptor sensitivity in dark adapted conditions, as ionic alteration of sensitivity to a steady background tends to cancel the measured alteration of sensitivity to the test stimulus. The reasons for this, and our methods for ensuring complete dark adaptation, have been described elsewhere¹⁴. Each V -log I curve required about 15 min, because of the stimulus spacing necessary to maintain dark adaptation. Following each change of solution, turnover in the perfusion chamber required less than 1 min. At least 5 min were always allowed before taking records, at which time the resting membrane potential and light responses had stabilised in the new solution. In Fig. 1 the value of $[\text{Ca}^{2+}]_o$ was at the control level of 1.8 mM for curve 1, then elevated to 6.0 mM for curve 2, returned to 1.8 mM for curve 3, lowered to 0.3 mM for curve 4, and again returned to 1.8 mM for curve 5. Each smooth curve in Fig. 1 is the computer-generated best fit to the data points, using the method of least squares and the Naka-Rushton equation, $V/V_{\max} = I^n / (I^n + \sigma^n)$. In this equation, V is the peak response amplitude elicited by a given stimulus intensity, I , and $V_{\max}$ is the maximum (saturated) response amplitude. The constant, σ , is the stimulus intensity eliciting a response of one-half the maximum amplitude, and in normalised curves the constant, n , is proportional to the slope at σ .

As previously demonstrated¹¹, and confirmed by us, the effects of light adaptation on the V -log I curve of toad rods include a reduction of $V_{\max}$, a reduced slope of the rapidly rising central portion of the curve, and a shift of σ to the right (towards higher intensities). Figure 1 shows that all these effects were mimicked by increasing $[\text{Ca}^{2+}]_o$ from 1.8 to 6.0 mM, whereas lowering $[\text{Ca}^{2+}]_o$ from 1.8 to 0.3 mM had the opposite effects. After the supra-normal $[\text{Ca}^{2+}]_o$, curve 3 shows almost complete recovery on return to the control solution. Following the sub-normal $[\text{Ca}^{2+}]_o$, curve 5 shows a more distinct loss of response amplitude on return to the control solution. In another experiment, however, when we waited 30 min after returning from 0.3 mM to 1.8 mM of $[\text{Ca}^{2+}]_o$, the final curve closely matched the initial control curve. As the effects of elevated and lowered

$[Ca^{2+}]_o$ were reversible, they apparently did not damage the photoreceptors. Effects of both elevated and lowered $[Ca^{2+}]_o$ have been tested in 10 different cells, and the results have been highly consistent. When $[Ca^{2+}]_o$ was increased from 1.8 to 6.0 mM the σ shift averaged +0.26 log units, and when $[Ca^{2+}]_o$ was lowered from 1.8 to 0.3 mM the σ shift averaged -0.49 log units. In both cases the s.e.m. was 0.04 log units. These σ shifts seem highly significant, as they show that altered $[Ca^{2+}]_o$ can mimic this important aspect of adaptation, with σ serving as a conventional index of the position of the V -log I curve on the intensity axis.

Fig. 1 Effects of $[Ca^{2+}]_o$ on the V -log I curve recorded intracellularly in the outer segment of a dark adapted red rod. Each point represents peak response amplitude. For each curve, responses were recorded in the order of increasing intensity. The sequence of curves is indicated by the numbers at the right. $[Ca^{2+}]_o$ was 0.3 mM for curve 4, 1.8 mM for curves 1, 3 and 5, and 6.0 mM for curve 2. A circular stimulus spot was centred on the electrode tip and focused on the outer segments, using direct viewing with infrared light in the stimulus beam. The stimulus spot was 1.0 mm in diameter at the outer segments, which more than covered the rod's receptive field¹⁷. Flashes of 500 nm light were 100 ms in duration, with a sufficient interval after each flash to maintain dark adaptation¹⁴. Stimulus intensities are expressed in photons absorbed per rod-flash, as described elsewhere¹⁴. The recording bandpass was 0–30 Hz, which did not affect response time course or amplitude. The resting membrane potential in control solution was -38 mV and showed no significant change during the experiment. In elevated $[Ca^{2+}]_o$ the membrane hyperpolarised by about 1.0 mV, and in lowered $[Ca^{2+}]_o$ depolarised by about 6.0 mV. With raised $[Ca^{2+}]_o$ the value of n remained constant at the control value of 0.75, so in high $[Ca^{2+}]_o$ the reduced slope of the V -log I curve resulted only from the decrease of V_{max} . In lowered $[Ca^{2+}]_o$ the value of n increased to 0.86, which contributed part of the observed increase in slope of the V -log I curve.

In their work on toad rods, Lipton *et al.* observed effects of $[Ca^{2+}]_o$ on V_{max} and the slope of the V -log I curve that were similar to the effects reported here. We therefore examined why they did not observe effects of altered $[Ca^{2+}]_o$ on the value of σ , even when the preparation was reported to be dark adapted. First, our perfusate contained 15 mM of bicarbonate, which was used for buffering. The perfusate of Lipton *et al.* contained only 0.13 mM of bicarbonate, and buffering was done with HEPES.

Our higher bicarbonate concentration seems preferable, as it is based on a plasma analysis in *Bufo marinus*¹³. Also, there is evidence that a bicarbonate concentration of about 25 mM is required in some other vertebrates for maintaining normal function of either photoreceptors¹⁵ or the adjacent pigment epithelium¹⁶. When both solutions were tested on the same cells, our control perfusate yielded V -log I curves with significantly higher values of V_{max} than obtained in the control perfusate of Lipton *et al.* When $[Ca^{2+}]_o$ was raised to 6.0 mM or lowered to 0.3 mM, we found σ shifts in their perfusate, but these were smaller and less consistent than those obtained in our own perfusate. Second, Lipton *et al.* increased $[Ca^{2+}]_o$ to only 3.2 mM, which we found to have little effect on σ , whereas our higher value of 6.0 mM was significantly more effective. Third, Lipton *et al.* used 1.0 mM of EGTA to produce a very low $[Ca^{2+}]_o$ of about 10^{-9} M. As demonstrated by them, and confirmed by us, this results in a continuous loss of sensitivity until the cell is almost completely unresponsive. As this occurred, they showed that the value of σ in the V -log I curves moved rapidly to the right. Their earliest curve was taken between 4 and 6 min after starting superfusion with the low $[Ca^{2+}]_o$; this was the curve chosen for comparison with the control solution and which showed no σ shift from control conditions. By extrapolation, curves taken at earlier times would be expected to show a σ shift to the left, but such curves were not shown. It is not clear why a given curve was chosen, from a rapidly changing set of curves, for comparison with the curve taken in normal $[Ca^{2+}]_o$. Fourth, our results indicate that a V -log I curve cannot be obtained within 2 min without significantly light adapting the cell by the test stimuli. Hence, if the low $[Ca^{2+}]_o$ of Lipton *et al.* shifted σ to the left, this may have been masked by a light adaptive shift of σ to the right. Because of these problems in very low $[Ca^{2+}]_o$, our approach was to use a subnormal value of $[Ca^{2+}]_o$ that was sufficiently low to yield clear effects but not low enough to cause continuous loss of sensitivity. The value of 0.3 mM proved adequate for this purpose, as it provided a steady-state condition during which a fully dark adapted V -log I curve could be obtained.

Thus, our results indicate that alteration of $[Ca^{2+}]_o$ can control the value of σ in the V -log I curve of toad rods. These results are consistent with a role for $[Ca^{2+}]_o$ in the control of sensitivity in vertebrate photoreceptors. Hence, changes of $[Ca^{2+}]_o$ may partially control the changes of sensitivity that occur during light and dark adaptation.

We thank Ms L. Belzer for technical assistance. This work was supported by the National Eye Institute.

Irazepine, a noncompetitive, irreversible inhibitor of ^3H -diazepam binding to benzodiazepine receptors

THE identification and characterisation of stereospecific, high-affinity binding sites for benzodiazepines in the mammalian CNS has been described both *in vivo*¹⁻³ and *in vitro*⁴⁻⁶. The correlations obtained between the *in vitro* affinities of a series of benzodiazepines for these binding sites and their clinical potencies as muscle relaxants², anxiolytics⁶ and anticonvulsants⁶ strongly suggest that these sites are pharmacological receptors mediating the therapeutic actions of the benzodiazepines. Benzodiazepines such as clonazepam, oxazepam and flurazepam are rapidly reversible, competitive inhibitors of ^3H -diazepam binding to synaptosomal membranes^{7,8}. Competitive inhibition of ^3H -diazepam binding has also been observed with the triazolopyridazines, which possess both anticonvulsant and anxiolytic activity⁹, and with the purines inosine and hypoxanthine^{10,11}, which may be endogenous ligands to the benzodiazepine receptor¹⁰⁻¹⁴. The development of noncompetitive, irreversible ligands has been invaluable in the characterisation, isolation and purification of both peripheral and central neurotransmitter receptors¹⁵, and may also prove useful for studying the benzodiazepine receptor. We now report the synthesis of a novel benzodiazepine, irazepine, which acts as a noncompetitive, irreversible inhibitor of ^3H -diazepam binding to synaptosomal membranes.

Irazepine [1-(2-isothiocyanatoethyl)-7-chloro-1,3-dihydro-5-(2-fluorophenyl)-2H-1,4-benzodiazepine-2-one] (Fig. 1a) was prepared as follows. A mixture of 203 mg (0.5 mmol) of Ro7-1986/1 (Fig. 1b), 10 ml of H_2O , 25 ml of CHCl_3 and 252 mg (3 mmol) of NaHCO_3 was stirred vigorously for 10 min, and then treated with 80.5 mg (0.7 mmol) of redistilled thiophosgene. Following vigorous stirring for 60 min, the CHCl_3 layer was separated, washed with 10 ml H_2O , dried with MgSO_4 and evaporated to give 182 mg of irazepine as a yellow foam. Thin layer chromatography of this material (silica gel GF, ether, ultraviolet visualisation) revealed essentially only one spot. The yellow foam was dissolved in 3 ml of warm isopropanol, rendered acidic with a slight excess of HCl gas and cooled to give 164 mg (80% yield) of crystalline irazepine·HCl. This material was recrystallised from methanol-diethyl ether to give analytically pure material: melting point (m.p.), 217–220 °C; mass spectrum, m/e 373/375 (M^+), infrared ν_{max} 2,110 cm^{-1} (NCS). Analysis: calculated for $\text{C}_{18}\text{H}_{14}\text{Cl}_2\text{FN}_3\text{OS}$: C, 52.69; H, 3.44; N, 10.24. Found: C, 52.42; H, 3.65; N, 10.14. In another preparation, the foamy residue from evaporation of the CHCl_3 extract was crystallised from isopropanol to give 151 mg (80% yield) of irazepine as the crystalline base, m.p. 142–144 °C. This material was readily recrystallised from absolute ethanol to give pure irazepine, m.p. 144.5–146 °C.

Specific binding of ^3H -diazepam to crude synaptosomal fractions of rat cerebral cortex was determined as described previously¹⁶, with the following modifications. Synaptosomal

Fig. 1 Structure of irazepine (a), Ro7-1986/1 (b) and presumed reaction products (c, d) with bionucleophiles.

Fig. 2 Scatchard analysis of ^3H -diazepam binding to rat synaptosomal membranes in the presence of: a, irazepine·HCl (20 nM) (○), control (●); b, Ro7-1986/1 (6 nM) (○), control (●). Dixon plot of ^3H -diazepam binding in the presence of variable concentrations of c, irazepine·HCl, 2.88 nM (○) and 6.77 nM (●); d, Ro7-1986/1: 3.33 nM (○) and 7.03 nM (●). Plots are representative experiments; individual data points were determined in triplicate for total binding and duplicate for nonspecific binding (see ref. 16).

membranes were incubated with irazepine·HCl, Ro7-1986/1, clonazepam or distilled water at 0–4 °C for 30 min before addition of ^3H -diazepam. The incubation was then continued for 20 min at 0–4 °C, and terminated by filtration as described previously. Clonazepam (final concentration 1 μM) was used to determine nonspecific binding.

The inhibition of ^3H -diazepam binding by Ro7-1986/1 and irazepine was characterised *in vitro* by Scatchard and Dixon analyses (Fig. 2). No significant change in the maximum number of binding sites (B_{max}) was observed when synaptosomal membranes were incubated with Ro7-1986/1, whereas there was a concentration-dependent decrease in the apparent affinity using between 6 and 18 nM Ro7-1986/1 (Fig. 2b and unpublished observations). In contrast, incubation of tissue with irazepine·HCl (20 nM) resulted in a significant reduction in B_{max} ($21.4 \pm 3.8\%$ reduction in five experiments; $P = 0.02$) and a consistent but not statistically significant increase in K_d (3.7 ± 0.3 nM compared with 4.6 ± 0.5 nM; $P = 0.1$) (Fig. 2a). These findings are consistent with a competitive inhibition of ^3H -diazepam binding by Ro7-1986/1 and a noncompetitive inhibition by irazepine HCl. These observations were confirmed by Dixon analyses of the inhibition of ^3H -diazepam binding by the two compounds (Fig. 2c,d). The K_i values for Ro7-1986/1 and irazepine·HCl were estimated to be 5.4 and 66 nM, respectively.

The noncompetitive inhibition of ^3H -diazepam binding by irazepine indicated that the binding of this ligand, in contrast to that of other benzodiazepines, may be irreversible. Thus, the binding of ^3H -diazepam was then studied in the presence of

fixed concentration of irazepine-HCl and a variable amount of receptor (tissue) (see ref. 17) in a manner analogous to that used for determination of enzyme inhibition by noncompetitive inhibitors. The effects of increasing receptor (tissue) concentrations on the inhibition of ^3H -diazepam binding by irazepine-HCl suggest an irreversible inhibitor (Fig. 3). These observations are further supported by the ready reaction of irazepine with certain model bionucleophiles.

To determine the reactivity of irazepine with model bionucleophiles ($-\text{NH}$, $-\text{SH}$ and $-\text{OH}$ groups) *in vitro*, irazepine base was treated in 70% aqueous ethanol (at 25 °C) with an excess of compounds containing these functional groups. The relative velocity of the reactions was monitored by observing the disappearance of irazepine by thin-layer chromatography. Irazepine reacted rapidly with both diethylamine and methyl mercaptoacetate. These reactions were virtually complete in less than 5 min, presumably yielding (Fig. 1) the corresponding thiourea (Fig. 1c, $\text{R}_1 = \text{N}(\text{C}_2\text{H}_5)_2$) and the dithiocarbamate (Fig. 1c, $\text{R}_1 = \text{S}-\text{CH}_2\text{CO}_2\text{CH}_3$) derivatives, respectively. In contrast, reduced glutathione reacted slowly with irazepine in these conditions; a substantial amount of irazepine remained after 24 h. Little, if any, reaction of irazepine with 70% ethanol was observed after 24 h. The reaction of the isothiocyanate function with primary and secondary amines as well as with mercaptans has been described (for review, see ref. 18), and with aliphatic amines the reaction is usually quite rapid¹⁹. These observations suggest that a covalent binding of irazepine to the benzodiazepine receptor could occur by reaction with a free amino or sulphhydryl group, for example, from a lysine or cysteine residue, yielding a thiourea or dithiocarbamate (as in Fig. 2d, $\text{X} = \text{NH}$ or S , respectively). These *in vitro* studies do not, however, exclude a covalent link between irazepine and other bionucleophiles possibly associated with the receptor (such as a hydroxy or guanidino moiety).

Our data suggest that in the conditions used, irazepine is a noncompetitive, irreversible inhibitor of ^3H -diazepam binding. This activity is unique, as the binding of other benzodiazepines,

Fig. 3 Determination of irreversible nature of irazepine binding to benzodiazepine receptors *in vitro*. Ordinate: specific binding (fmol per mg protein); abscissa: μl of receptor (tissue) added. Incubations were performed as described in text. Upper line: observed points for control incubations (no irazepine); middle line: theoretical line for a noncompetitive reversible inhibitor, assuming the lines should pass through the origin and the 1,000 μl per incubation point. Bottom line: observed points in the presence of 100 nM irazepine-HCl. The line generated in the presence of irazepine indicates irreversible binding, analogous to determination of reversible/irreversible nature of enzyme inhibitors (see ref. 17) at low concentrations that is, of receptor, virtually no binding of ^3H -diazepam is observed. ○, Irazepine; ●, control; ---, reversible (expected).

triazolopyridazines and purines to the benzodiazepine receptor⁷⁻¹¹ is competitive. Irazepine is potentially useful in receptor isolation and purification, biochemical characterisation and histochemical localisation of the receptor, as well as estimation of receptor turnover *in vivo*. Further studies will be necessary to test the usefulness of this compound as a probe of the benzodiazepine receptor.

We thank V. Moncada and M. Mattson for technical assistance. Clonazepam and Ro7-1986/1 were provided by Dr W. Scott, Roche.

Collagenous bone matrix is a local mitogen

THE importance of collagens in growth and differentiation^{1,2} and in cell adhesion³ is well documented. We have previously shown that cell-free, demineralised, collagenous bone matrix induces the formation of cartilage, bone and bone marrow⁴⁻⁶. One of the early responses to implanted collagenous matrix is the appearance of connective tissue mesenchymal cells adjacent to the implanted matrix before their differentiation into cartilage. We present here direct evidence that collagenous bone matrix is a local mitogen for connective tissue cells. We find that the collagenous bone matrix is a potent inducer of ornithine decarboxylase (EC 4.1.1.17, ODC), an enzyme involved in polyamine biosynthesis⁷ and considered as an early marker of cell proliferation⁸. These studies have been corroborated by incorporation of ^3H -thymidine into acid-precipitable material and by autoradiography. Our results reveal the local influence of insoluble collagenous bone matrix on proliferation of mesenchymal cells and imply a role for this extracellular matrix in anchorage-dependent⁹ events in cell growth and differentiation.

Demineralised bone matrix powder prepared from rat diaphyses was transplanted subcutaneously in the anterior thoracic region of 28-35-d-old, male rats of Long-Evans strain

Fig. 1 Changes in the concentration of DNA (a), ornithine decarboxylase (b) and ³H-thymidine incorporation (c) during collagenous matrix-induced endochondral bone development. Plaques from individual rats were homogenised in ice-cold buffer containing 50 mM Tris-HCl, 10 mM dithiothreitol and 1 mM EDTA at pH 7.4, and centrifuged for 30 min at 30,000 g. ODC in the supernatant was determined by the method of Jänne and Williams-Ashman¹⁰; protein was determined according to Lowry *et al.*¹³. ³H-thymidine incorporation and DNA content were determined as described in the text. Day 1, polymorphonuclear leukocytes; day 3, fibroblasts; day 7, cartilage; day 11, bone; day 19, bone marrow.

as described previously⁴. The day of transplantation was designated as day 0. On different days after transplantation, the rats were injected intravenously with ³H-thymidine at a dose of 1 μCi per g body weight, 2 h before the end of the experiment. At autopsy the plaques were dissected free of adhering tissue; one portion from each plaque was used for determination of the activity of ODC^{10,11}, and another portion was processed for autoradiography by conventional methods with Kodak NTB-3 nuclear track emulsion. The rest of the plaque was homogenised in cold 10% trichloroacetic acid (TCA) containing 1 mM thymidine, and the incorporation of ³H-thymidine into acid soluble and insoluble portions was determined. Following acid hydrolysis, DNA in the TCA extract was measured. Calf thymus DNA served as the standard¹². The results were statistically evaluated by means of the Student's *t* test.

On day 3 collagenous bone matrix induced an increase in the ODC activity (Fig. 1b), which correlated with the incorporation of ³H-thymidine into the acid-precipitable fraction (Fig. 1c). Autoradiography at the light microscope level revealed cells labelled with ³H-thymidine in the vicinity of the implanted matrix (Fig. 2a). The high content of DNA on day 1, as determined by the diphenylamine method¹², is attributed to migration of polymorphonuclear leukocytes into the implant site, because there was no detectable incorporation of ³H-thymidine. There was a decline in both ODC activity and ³H-thymidine incorporation on days 5–7, when cartilage differentiation was in progress. On days 8–9 there was a second

peak of proliferation of cells (Fig. 2b) before impending osteogenesis and vascular invasion, as indicated by a peak of ODC and ³H-thymidine incorporation (Fig. 1). The ODC activity then steadily declined, but incorporation of ³H-thymidine continued and increased further during haematopoiesis on days 18–21. This increased incorporation was correlated with an increase in accumulated DNA as determined by a chemical procedure¹².

The proliferative response to collagenous bone matrix seems to be quite specific, because collagenous matrix from rat tail tendon is weak in this respect¹¹. It is worth recalling that tendon matrix is incapable of inducing endochondral bone¹.

The mechanism(s) underlying the local mitogenic action of the collagenous bone matrix is not known. Although the role of soluble growth factors in cell proliferation has been studied¹⁴, virtually nothing is known about the role of insoluble, extracellular, matrix macromolecules such as collagen and associated components. In many tissues collagenous matrix is the extracellular framework with which cells interact. The importance of collagenous matrix in development and differentiation and in the specification of positional information has been emphasised earlier¹. Recent investigations show that collagen is required for the proliferation of normal connective tissue cells but not for their transformed counterparts¹⁶. The study of skeletal and dental tissues, which abound with these constituents, may provide important clues to the possible function of the extracellular collagenous matrix and its associated components. The cellular

Raven Press

JOURNAL OF CARDIOVASCULAR PHARMACOLOGY

Editors-in-Chief: J. Koch-Weser and W. Pettinger

An international, multidisciplinary journal devoted to furthering the exchange of new information on cardiovascular pharmacology.

Published bimonthly beginning January 1979.
Volume 1: \$48.00 U.S.A.; \$56.00 Elsewhere

METHODS IN PROSTAGLANDIN RESEARCH

(Advances in Prostaglandin and Thromboxane Research, Vol. 5)

Editor: J. C. Frölich

A practical manual for the laboratory, this book describes in full detail methods that are currently in use in the discovery, identification, and quantitation of prostaglandins, thromboxanes, prostacyclin, and their precursors and metabolites. The book is

extensively cross-referenced and indexed, making it a source of ready reference.

250 pages (1978) \$31.20

ADVANCES IN CYCLIC NUCLEOTIDE RESEARCH (Vol. 10): CURRENT METHODOLOGY

Editors: G. Brooker, P. Greengard, and G. A. Robison

This is a complete and detailed review of the current methodology used in studying the cyclic nucleotides and their biological effects. The detailed instructions for the methods, including the needed

materials and discussions of problems and techniques to check assay validity, will be invaluable.

250 pages (1979) \$31.20

GLUTAMIC ACID: BIOCHEMISTRY AND PHYSIOLOGY

Editors: L. J. Filer, Jr., S. Garattini, M. R. Kare, W. A. Reynolds and R. J. Wurtman

This volume reviews the sensory and dietary aspects of glutamate, its metabolism in mammals, its role in the central nervous system,

an evaluation of its safety and experimental application, and clinical aspects of glutamate utilization.

425 pages (1979) \$36.40

NEUROCHEMICAL MECHANISMS OF OPIATES AND ENDORPHINS (Advances in Biochemical Psychopharmacology, Vol. 20)

Editors: H. H. Loh and D. H. Ross

This volume provides a comprehensive review of the rapidly expanding field of opiate research and the current state of our

understanding of the neurochemical mechanisms of opiate and endorphin actions.

570 pages (1979) \$51.35

Advances in Cyclic Nucleotide Research, Volume 9 THIRD INTERNATIONAL CONFERENCE ON CYCLIC NUCLEOTIDES New Orleans, Louisiana, U.S.A. July 17-22, 1977

Editors: W. J. George and L. Ignarro

cascade accompanying the collagenous bone matrix-induced formation of endochondral bone^{1,4-6} is remarkably similar to that seen during fracture healing in man. Collagens and their peptide constituents are chemotactic to fibroblasts¹⁵. The present study provides evidence that collagenous matrix from bone has a local mitogenic action. These observations may explain the local nature of fracture- and wound-healing responses and also provide a basis for further studies in clinical areas such as dental implants and periodontal diseases.

Mutagenesis *in vitro* by DNA polymerase from an RNA tumour virus

THE fidelity of DNA synthesis has usually been determined from polynucleotide templates of restricted base composition¹⁻³. Mis-matched nucleotides were simply identified as those non-complementary to the template. Error rates estimated in this way are less than were predicted on the basis of Watson-Crick base pairing, 10^{-2} (refs 4-6), but greater than were inferred from spontaneous mutation frequencies, 10^{-8} - 10^{-11} (ref. 7). However, *in vitro* error rates measured for the same enzyme vary from one synthetic template to another^{3,8,9}. In addition, the repeating structure of homopolymers and copolymers may, by slippage and looping-out of mis-matched bases¹⁰, allow a higher frequency of mis-pairing than natural DNA of random sequence. To avoid these problems, we have recently developed a method for measuring the accuracy of *in vitro* DNA synthesis using a natural DNA template¹¹. We now report that a DNA polymerase which has a high frequency of mis-incorporation with synthetic polynucleotides¹ is also mutagenic when copying natural DNA *in vitro*.

Briefly, mutagenesis is measured *in vitro* with biologically active DNA in the following way. The template is the single-stranded circular DNA from bacteriophage Φ X174 and contains one nucleotide substitution mutation (*am3*) located in the overlapping genes *D* and *E* (refs 12, 13). Synthesis is initiated on a DNA restriction fragment (*Hae*III Z-5) hybridised to the template. The 3'-OH terminus of Z-5 is located 83 nucleotides from the *amber* mutation¹³. Purified DNA polymerase from any source may be used to copy the DNA in defined *in vitro* conditions. The accuracy with which the DNA polymerase has copied the *amber* mutation is then measured by

Fig. 1 Sedimentation of Φ X174 DNA after copying by AMV DNA polymerase. ^3H -labelled *am3* Φ X174 DNA was hybridised to the Z-5 restriction fragment and copied by AMV DNA polymerase as indicated in the legend to Table 1. A 20- μl sample of the reaction mixture after termination with EDTA (before top annealing) was applied to a 5-20% neutral sucrose gradient containing 10 mM Tris-HCl (pH 7.5), 10 mM EDTA, 1.0 M NaCl and 0.1% sarkosyl. Gradients were centrifuged at 45,000 r.p.m. at 20°C for 16 h in a Spinco SW 50 rotor. Fractionation of the gradients was from the top, and the total amount of radioactivity present in each fraction was determined after adding 50 μl calf thymus DNA (1 mg ml⁻¹), 1 ml 5% trichloroacetic acid and collecting the precipitates on glass fibre filters. ^3H -radioactivity was determined after the ^{32}P -radioactivity had decayed for 4 weeks. The ss DNA marker was single-stranded ^3H - Φ X DNA. The ds DNA marker was ^{14}C -labelled double-stranded Φ X DNA. In control experiments, the single-stranded Φ X174 DNA hybridised to the Z-5 fragment sedimented coincidentally with the single-stranded Φ X174 DNA marker.

transfection. The copied DNA is used to infect *Escherichia coli* spheroplasts. Accurately copied DNA will contain the *amber* codon in both parent and daughter strands, and give rise to mutant phage only. Inaccurately copied DNA will contain mis-matched bases, some of which will code for a revertant daughter strand at the *am3* codon. The fidelity of DNA synthesis *in vitro* is obtained from the reversion frequency of the phage produced from copied DNA.

Φ X *am3* DNA was copied by homogeneous avian myeloblastosis virus (AMV) DNA polymerase in the presence of 8 mM MgCl₂ and 100 μM of each of the deoxynucleoside triphosphates and then used to infect *E. coli* spheroplasts. The infected spheroplasts were immediately plated onto indicator bacteria either permissive or non-permissive for *am3*, to determine how many infective centres produced mutant *am3* phage and how many revertant phage (Table 1). *am3* DNA copied by AMV DNA polymerase produced phage with an average reversion frequency of 25.8×10^{-5} . This is about 4.5 times higher than the average background reversion frequency, 5.76×10^{-5} , which results from infection by the same *am3* DNA template incubated with reaction mixture in the absence of DNA polymerase. These results indicate that copying by AMV

am3 Φ X DNA was copied *in vitro* at 37°C for 45 min in a 50- μ l reaction mixture containing 40 mM Tris-HCl (pH 7.5), 5 mM dithiothreitol, 8 mM MgCl₂, 2×10^{11} molecules of Φ X174 *am3* single-stranded DNA hybridised to an *am3* *Hae*III Z-5 fragment, 100 μ M each of dATP, dGTP, dCTP and [α -³²P]dTTP (specific activity, 200 d.p.m. pmol⁻¹), and 10 pmol of purified AMV DNA polymerase. Synthesis was terminated by the addition of EDTA to 20 mM, and acid-precipitable counts were determined on aliquots of 2 μ l. The number of nucleotides incorporated per template was determined by dividing the number of nucleotides incorporated by the number of Φ X template molecules added to the reaction mixture (5,376 nucleotides per genome). The remainder of the copied DNA was hybridised to *Hae*III restriction fragments from *am3* Φ X DNA ('top annealing', ref. 11) and used to infect spheroplasts from *E. coli* KT-1 (su⁺, λ ⁻, Φ X^r) as described by L.A.W. and L.A.L.¹¹ In experiments 5 and 6, top annealing was unnecessary¹⁹. The infected spheroplasts were immediately plated onto indicator bacteria *E. coli* HF 4704 and *E. coli* 4714 (restrictive and permissive for the *amber* codon) to assay the number of wild-type and total infective centres. Uncopied DNA was subjected to exactly the same conditions except that DNA polymerase was omitted from the reaction mixture. The AMV DNA polymerase used in this study was purified to homogeneity from isolated virions by the method of Kacian *et al.*²⁰. The preparation used was free of detectable DNA, endonuclease, exodeoxyribonuclease and DNA ligase²¹.

DNA polymerase has led to an increased frequency of back mutations (revertants) on the Φ X DNA.

To calculate the frequency of revertants in the daughter DNA strand from the reversion frequency of the phage after infection, it is necessary to correct for penetrance, the frequency with which the *in vitro* synthesised DNA strand is expressed in the progeny phage. A value of 0.13 ± 0.06 was obtained from six experiments in which spheroplasts were infected with *am3* Φ X (+)strand DNA circles hybridised to a saturating concentration of wild-type restriction fragments (*Hae*III Z-7) which cover the *am3* codon¹¹. The calculated error rates of DNA synthesis past the *am3* mutation by AMV DNA polymerase therefore averaged 1 in 904 in the six determinations (Table 1).

Our calculations assume that every infecting Φ X DNA molecule contained a daughter DNA strand which extended at least past the *am3* codon. This assumption was tested by sedimentation analysis of the Φ X DNA product following *in vitro* synthesis by AMV DNA polymerase. The single-stranded Φ X DNA template was labelled with tritium and synthesis was monitored by incorporation of [α -³²P]dTTP. The DNA product, copied to the extent of an average of 1,050 nucleotides per added template, was sedimented in a neutral, high salt sucrose gradient. In these conditions, Φ X DNA circles migrate as double-stranded molecules when they are replicated 20% or more¹⁴. After synthesis, 70% or more of the templates and all of the product sediment coincidentally with double-stranded Φ X174 DNA (Fig. 1). (The Z-5 primer plus the 83 nucleotides to the end of the *am3* codon constitute 393 nucleotides, or only 7.3% of the 5,376 nucleotide-long genome¹³.) To the degree that some molecules of template remain uncopied, the error rate could be underestimated by as much as 30%.

These experiments represent the first estimate of the error rate with which AMV DNA polymerase copies a natural DNA template *in vitro*. The error rates are similar to those observed with homopolymer templates. This measurement with Φ X DNA does not take into account substitutions at the *amber* codon that are lethal, or the effects of substitutions at other positions on the genome. Studies with *E. coli* DNA polymerase

in mutagenic conditions indicate that distant incorrect substitutions invariably decrease the observed reversion frequency at the *am3* codon (T.A.K. and L.A.L., unpublished results). Thus, the error rates reported represent a minimum value.

The high error rate observed in copying natural DNA, one mismatch per 1,000 nucleotides polymerised, is nearly one order of magnitude greater than that observed in initial experiments with *E. coli* DNA polymerase I, 1 in 6,000 to 1 in 20,000 (ref. 11 and T.A.K. and L.A.L., unpublished results). However, we have observed certain preparations of AMV DNA polymerase which copy both poly (dA-dT) and Φ X DNA at lower error rates. The different error rates among different preparations of AMV DNA polymerase might be due to the degree of phosphorylation of the enzyme itself. A protein kinase has been purified from AMV which is able to phosphorylate AMV DNA polymerase, thereby increasing the rate of catalysis¹⁵. The *sarc* gene, the viral gene responsible for transformation in culture and the induction of sarcomas in animals, has been demonstrated to be a protein kinase¹⁶.

Because DNA polymerases from AMV and other RNA tumour viruses seem to be highly error prone *in vitro*, we may ask whether RNA tumour viruses have a correspondingly high mutation rate *in vivo*. This correspondence would be consistent with the hypothesis of Eigen and Schuster¹⁷ relating error rate of replicating enzymes to genome size. A spontaneous mutation rate in the host-range marker in the RNA tumour virus B77 has been measured to be about 1 per 100 pro-virus replications¹⁸ and a similarly high mutation rate has been observed in the *sarc* gene of other strains of Rous sarcoma virus (B. Mason and D. K. Dube, unpublished results). These high spontaneous *in vivo* mutation rates observed for RNA tumour viruses may in part be caused by the viral DNA polymerase which frequently incorporates mis-matched nucleotides during DNA synthesis. The ability of DNA polymerases to copy DNA templates from any source has led to the hypothesis that DNA polymerases from oncogenic viruses copy host DNA inaccurately, causing mutations and initiating tumorigenesis⁶.

Ribose methylation and resistance to thiostrepton

THE antibiotic, thiostrepton, produced by *Streptomyces azureus*, inhibits bacterial protein synthesis by binding to 50S ribosomal subunits with 1:1 stoichiometry. Recently¹, we showed that *S. azureus* prevents its own death by methylating 23S ribosomal RNA (rRNA) so that its ribosomes do not bind the drug. Intact ribosomes are not substrates for the methylase and those experiments involved methylation of 'core particles' derived from the (thiostrepton-sensitive) ribosomes of *Streptomyces coelicolor*. Ribosomes can be reconstituted from core particles by adding back the missing 'split proteins'. Presumably, in *S. azureus*, methylation of 23S rRNA occurs before assembly of the 50S ribosomal subunit is completed. Here we report that the 'thiostrepton-resistance' methylase of *S. azureus* is an RNA-ribose methylase which introduces a single methyl group into adenosine in 23S rRNA. This is a novel antibiotic-resistance mechanism.

Crude methylase was prepared from *S. azureus* as previously described¹ and was used to methylate 3 M LiCl core particles from *S. coelicolor* ribosomes together with *S*-adenosyl[methyl-³H]methionine cofactor. As shown in Fig. 1, ³H-methyl groups were incorporated into at least three different residues in rRNA one of which predominated greatly over the others. Acid hydrolysates of rRNA prepared as in Fig. 1 contain mainly purine

bases, pyrimidine nucleoside monophosphates and ribose phosphate. When the major peak of radioactivity was eluted from chromatograms such as that shown in Fig. 1 and incubated with acid phosphatase, the resultant material was not adsorbed by activated charcoal (thus, it did not contain a purine or pyrimidine base) and did not migrate on high voltage paper electrophoresis (HVPE) at any pH between 2.5 and 10.5. We therefore concluded that the major methylated product visualised in Fig. 1 was 2'-*O*-methylribose-5'-phosphate and that it had probably been derived from a purine nucleotide in rRNA. The minor methylated products in Fig. 1 were purine bases and we have identified one as *N*⁶-methyladenine (data not given).

The stoichiometry of methylation of *S. coelicolor* ribosomal core particles by *S. azureus* crude methylase corresponded at saturation to 1.1–1.2 methyl groups incorporated per core (Fig. 2). Because in Fig. 1 ~85% of the ³H-methyl groups incorporated were recovered in the major product (2'-*O*-methylribose phosphate), we concluded that this material had been produced to the extent of one residue per core particle. In contrast, the more abundant of the minor products (*N*⁶-methyladenine) occurred on average only once per 7.5–8.0 core particles. As core particles methylated in these conditions completely lost the ability to support thiostrepton binding (after reconstitution with split proteins), we concluded that a causal connection exists between ribose methylation and resistance to the drug. This conclusion was supported by the observation (Fig. 2) that the time courses of methylation and acquisition of resistance to thiostrepton were superimposable. In other experiments (data not given) we confirmed that methylribose phosphate was produced exclusively in 23S rRNA.

Fig. 1 Chromatography of acid hydrolysates of methylated rRNA from *S. coelicolor*. 500 pmol *S. coelicolor* 3 M LiCl cores (prepared as described previously¹) were incubated at 30 °C for 3 h with crude *S. azureus* methylase¹ together with 25 μ Ci *S*-adenosyl[methyl-³H]methionine (500 mCi mmol⁻¹). This was carried out in 1 ml of buffer containing 50 mM HEPES-KOH, pH 7.5 at 20 °C, 7.5 mM MgCl₂, 37.5 mM NH₄Cl, 3 mM mercaptoethanol. Cores were then extracted twice with water-saturated phenol and rRNA was precipitated from the aqueous phase with 2.5 volumes of ethanol at -20 °C for at least 2 h. Precipitation with ethanol was repeated after re-dissolving the RNA in 0.25 M sodium acetate. Hydrolysis of RNA in 1 M HCl was carried out for 60 min in a boiling water-bath and the hydrolysate was applied to Whatman 3 MM paper. Descending chromatography was carried out in solvent containing isopropanol-water-concorder UV light and radioactivity in sample tracks was estimated by liquid-scintillation spectrometry after cutting the tracks into strips 1 cm wide. '*N*⁶meA' represents *N*⁶-methyladenine; 'PRM', 2'-*O*-methylribose-5'-phosphate.

Fig. 2 Time courses of methylation and acquisition of thiostrepton resistance. **A**, Methylation: *S. coelicolor* cores were methylated as in Fig. 1 except that the incubation volume was reduced to 200 μ l. At the times indicated samples (20 μ l) were removed into 2 ml ice-cold 10% (w/v) trichloroacetic acid (TCA) and after 30 min at 0°C precipitates were collected on glass fibre disks (Whatman GFC). These were washed with 5 $\times$ 4 ml of 5% (w/v) TCA and dried before estimation of their radioactivity by liquid-scintillation spectrometry. Counting efficiency was approximately 26% so that 1 pmol of ^3H -methyl radioactivity gave 285 c.p.m. **B**, Thiostrepton resistance ($\circ$): *S. coelicolor* cores were methylated as in **A** above except that non-radioactive *S*-adenosylmethionine (0.5 mM final concentration) was used. Samples (20 μ l) containing 16 pmol of cores were removed as indicated and were incubated with a twofold excess of *S. coelicolor* 3 M LiCl split proteins (prepared as previously described¹) and then with ^{35}S -thiostrepton (35 pmol) as described earlier¹. Binding of ^{35}S -thiostrepton to reconstituted particles was assayed by gel filtration¹. The specific radioactivity of ^{35}S -thiostrepton was 1,053 c.p.m. pmol⁻¹. Results have been normalised. Cores do not bind ^{35}S -thiostrepton and reconstituted non-methylated particles do so with approximately 1:1 stoichiometry (this latter level of drug binding was taken as 100%).

The major methylated nucleoside produced in 23S rRNA by the action of *S. azureus* methylase was identified by a combination of paper chromatography and HVPE following digestion of the RNA with snake venom phosphodiesterase and bacterial alkaline phosphatase². Thus, the methylated nucleoside migrated as a single peak of radioactivity during paper chromatography in butanol-ammonia solvent (Fig. 3a). This procedure also served to deproteinise the nucleoside preparation so that, following elution from the paper and lyophilisation, it could be further analysed by HVPE. As shown in Fig. 3b, the methylated nucleoside migrated with adenosine and cytidine at pH 2.5 and was well separated from guanosine and uridine, which are uncharged at this pH. At pH 3.5 (data not given) cytidine migrated well ahead of adenosine and the methylated nucleoside co-migrated with the latter. Also, the methylated nucleoside remained at the origin during HVPE at pH 9.3 in borate buffer (data not given). In these latter conditions nucleosides containing non-methylated ribose migrate towards the anode as borate complexes. Further evidence that the methylated nucleoside contained 2'-*O*-methylribose was obtained by HVPE at pH 2.5 after heating in a boiling water bath for 20 min with 1M HCl (Fig. 3c). All the radioactivity which had previously migrated as a cation with adenosine (Fig. 3b) was now found to remain near the origin with uncharged markers (for example, ribose and deoxyribose). Accordingly, and because there was no reason to suppose that the adenine ring was modified in addition to ribose, we concluded that the methylated nucleoside under investigation was 2'-*O*-methyladenosine. (For the chromatographic properties of various base-modified adenosines see ref. 4.)

Ribose-methylation is a novel mechanism of resistance to an antibiotic. There are only two other examples of antibiotic resistance known to involve changes in the pattern of post-transcriptional modification of rRNA, and both of these involve base methylation. Thus, kasugamycin-resistant mutants (*ksgA* mutants) of *Escherichia coli* possess 16S rRNA which is under-methylated in comparison with wild type and lacks geminal residues of *N*⁶,*N*⁶-dimethyladenine normally located near the 3' terminus⁵. Conversely, certain strains of *Staphylococcus* and *Streptococcus*, which possess the so-called MLS phenotype

Fig. 3 Identification of methylated nucleoside. *S. coelicolor* 3 M LiCl cores (500 pmol) were methylated with the crude *S. azureus* methylase and *S*-adenosyl[methyl- ^3H]methionine and then RNA extracted as described in Fig. 1. RNA was dissolved in 25 ml 10 mM Tris-HCl, pH 8.0, and incubated for 18 h at 37°C with 2 mg crude snake venom phosphodiesterase (from *Crotalus atrox*) and at the same time 1.3 mg of bacterial alkaline phosphatase². Finally, the reaction mixture was lyophilised. **a**, The lyophilised digest, still containing protein, was dissolved in a minimum volume of water and applied to Whatman 3 MM paper for descending chromatography in solvent containing butanol:water:concentrated ammonia solution in the proportions 86:14:5. Routinely, such chromatograms ran 50 cm in 15–18 h (the full length of the paper) and were removed for drying after 20–24 h. Markers were detected under UV light and radioactivity in the sample tracks was estimated by liquid-scintillation spectrometry after cutting the tracks into strips 1 cm wide. Material corresponding to the single peak of radioactivity running on these chromatograms was eluted, lyophilised and taken up in water. This preparation of methylated nucleoside was further analysed by HVPE as described below and in the text. **b**, Methylated nucleoside was applied to Whatman 3 MM paper and subjected to HVPE using 50 mM glycine-HCl buffer, pH 2.5. Electrophoresis was for 45 min at 4,000 V in a flat-bed water-cooled apparatus very similar to one described elsewhere³. Detection of markers and of radioactivity in the sample track was carried out as above. **c**, Methylated nucleoside was hydrolysed by addition of an equal volume of 2 M HCl followed by immersion in a boiling water bath for 20 min. The hydrolysate was then subjected to HVPE at pH 2.5 as in **b**. Ribose and deoxyribose markers were detected by standard staining techniques. Following electrophoresis, uncharged markers such as ribose, deoxyribose and (at pH 2.5) uridine were located a short distance from the origin (**b**, **c**) due to endosmotic flow. Abbreviations: Ar and similar = nucleosides; Am = 2'-*O*-methyladenosine; *N*⁶meA = *N*⁶-methyladenine; *N*⁶-dimeA = *N*⁶,*N*⁶-dimethyladenine; r = ribose.

resistance to macrolide, lincosamide and streptogramin B-type antibiotics), possess 23S rRNA which is over-methylated. In this case, sub-lethal concentrations of erythromycin (a macrolide) induce the synthesis of a plasmid-encoded enzyme which produces approximately two residues of N^6,N^6 -dimethyladenine in 23S rRNA (ref. 6). Recently, there has been evidence to suggest the existence of a similar enzyme in *Streptomyces erythreus*, the organism which produces erythromycin⁷. The only other resistance phenotype known to involve some property of rRNA concerns resistance to viomycin in *Mycobacterium smegmatis*. Mutants of this organism possess lesions in either 16S or 23S rRNA, but the nature of such lesions is unknown⁸.

In conclusion, we note that whereas ribose methylation occurs only rarely in the rRNA of prokaryotes⁹ it occurs much more frequently in the rRNA of eukaryotes¹⁰. It is possible that the different sensitivities of prokaryotic and eukaryotic ribosomes to thiostrepton might ultimately be determined by patterns of ribose methylation in rRNA.

Lobster shell carotenoprotein organisation *in situ* studied by photoacoustic spectroscopy

A SINGLE carotenoid pigment, astaxanthin, bound to specific proteins in a complex quaternary structure, provides shell coloration in the lobster *Homarus americanus*¹⁻⁸. The absorption of light by these carotenoproteins is uniform over a remarkable spectral range, as evidenced by the reflectance of a blue shell fragment which is low (5-6%) and essentially constant from 400 to 700 nm (ref. 9). This uniform absorption cannot be assigned to any combination of the carotenoprotein complexes which have been isolated. To assess the significance of these chemical species and to make specific inferences about carotenoprotein function *in vivo*, it is essential to measure the absorption spectrum *in situ*¹⁰. Several astaxanthin-protein complexes which absorb in the visible region have been isolated and spectroscopically characterised^{1-9,11}. These include α - and γ -crustacyanin with absorption maxima at 632 and 625 nm, respectively, and a second complex called the yellow protein^{7,11} which absorbs maximally at 410 nm. An early *in situ* absorption measurement of a carapace sample taken immediately after ecdysis and before calcification has been reported by Cheesman *et al.*⁴. However, the absence of structure in the reflectance measurements⁹ from a mature, opaque carapace suggests that conventional spectroscopy can yield little information about absorption maxima *in situ*. By using a new spectroscopic technique, photoacoustic spectroscopy (PAS), we have obtained spectra of a native shell fragment and here report the existence of a near continuum of astaxanthin absorption energies which span the visible spectral region. Furthermore, these pigments are in an anisotropic distribution within the endocuticle, that is, those absorbing in the blue are near the surface whereas those absorbing in the red are in the interior.

Fig. 1 Photoacoustic absorption spectra of native (a) and denatured (b) lobster shell as a function of modulation frequency ω (indicated with each spectrum) and phase ϕ . The interior spectra (—) were recorded with ϕ selected for maximum discrimination against the surface signal. In this case, decreasing ω allows response from deeper within the sample. The surface region spectra (---) were recorded with ϕ selected for maximum response from the surface. This selection of phase angle restricts the response to the surface region and results in a spectrum which is essentially independent of ω . Square wave modulation used in our spectrometer results in a triangular waveform from a carbon black (soot) sample and a concomitant 90° phase shift from the reference. Thus, the surface spectrum is optimised at $\phi = 90^\circ$ and discriminated against at $\phi = 0^\circ$. These spectra were recorded with a 10 nm spectral bandpass and a 0.03 Hz bandwidth (4-s time constant) at the lock-in output. The signal intensities are only qualitative.

PAS is ideally suited for measuring absorption maxima of opaque materials, and as it depends on thermal as well as optical properties of the sample, provides different information from reflectance measurements. It involves the measurement of heat produced as an excited species relaxes by a nonradiative path¹²⁻¹⁸. The exciting light is chopped at a suitable frequency and the resulting modulated heat flow is detected as pressure fluctuations using a microphone and a lock-in amplifier. As the exciting light is scanned, a spectrum similar to the absorption spectrum is obtained in which the response is proportional to both the absorption cross section and the thermal diffusivity of the sample. It is convenient to specify a thermal diffusion length¹³, $\mu = (2\alpha/\omega)^{1/2}$, where α is the thermal diffusivity and ω the chopping frequency. The definition of μ is such that light which penetrates the sample deeper than μ before absorption does not contribute to the response, as the periodicity is damped out

before the heat diffuses to the surface. Additionally, the phase (ϕ) of the signal at the phase-sensitive detector is critically dependent on the thermal diffusion time, as phase shifts are induced by the time required for thermal diffusion to the sample surface¹⁵⁻¹⁷. Spectral band shapes are influenced by several factors including wavelength-dependent relaxation pathways, saturation effects¹⁴ and, in layered samples, the filter effect of pigments located near the surface. Nevertheless, band maxima from PAS agree very well with measurements by conventional absorption techniques, and the spectrum is independent of ω and ϕ for an isotropic sample, provided saturation is avoided¹⁴. A key feature of PAS is that both ϕ and μ are experimental parameters that can be chosen to optimise the response from different levels of the sample^{16,17}. In certain cases the pigment locations in anisotropic (layered) samples can be determined¹⁵.

The spectra presented here are of a small sample ($\sim 4 \text{ mm}^2$) of uniform deep blue-green colour which was removed from the carapace of a live, mature lobster and used without further preparation. Samples removed from regions of carapace of similar appearance yield indistinguishable results, and samples from regions of obviously different coloration, such as the yellow underside of the claw, yield distinctively different spectra.

Figure 1a presents a series of spectra obtained at different modulation frequencies and phases. It is immediately apparent that the pigment distribution in the carapace is anisotropic so that by changing ω and ϕ one gains access to the different classes (layers) of pigments. Beginning with the surface region, absorption in the near UV by the epicuticle (which consists of wax, polyphenols and various lipoproteins^{4,19}) is evident, together with a band at $\sim 425 \text{ nm}$ which is assigned to the outermost carotenoprotein in the endocuticle. The spectra from the interior of the endocuticle demonstrate a remarkable bathochromic shift in the carotenoprotein absorption, from ~ 450 to $\sim 625 \text{ nm}$, as the modulation frequency is lowered from 326 to 26 Hz. The exception to this trend is the band at 390 nm which is clearly evident in the 26 Hz spectrum and not present in the spectrum from the surface region.

Figure 1b presents the results of a similar study on the shell fragment after denaturation of the carotenoproteins by boiling. The surface region spectrum shows that although the absorption of the epicuticle remains unchanged, the carotenoprotein band at $\sim 425 \text{ nm}$ is shifted to $\sim 450 \text{ nm}$. Only a small change in the interior spectrum is observed as ω is changed. The absorption in the red has disappeared and there is a general appearance of absorption strength in the region 450–560 nm.

We propose that the progressive bathochromic shift of the pigment absorption as a function of depth in the native endocuticle is due to highly specific protein-protein, pigment-protein and pigment-pigment interactions. If this is correct, then it is expected that denaturation would tend to convert all the chromophores to a common form. Indeed, this is the case, and thus the observation of the expected spectra from the denatured sample strongly supports the assignment of an anisotropic distribution of bathochromically shifted pigments in the native endocuticle.

The assignment of bands observed *in situ* to crustacyanins which have been isolated and purified is not straightforward. The spectra presented here, as well as the reflectance spectrum, are characteristic of an essentially continuous shift in the absorption maximum of the crustacyanins. This shift is produced by the interactions described above, which are expected to be a part of the ultrastructure of the endocuticle. Thus, it may not be possible to isolate discrete chemical species corresponding to each absorption. In the case of the denatured shell, the range of absorption maxima between 450 and 560 nm is characteristic of β -crustacyanin and other products of the denaturation of α -crustacyanin^{2,7,8}.

Astaxanthin aggregates, which have been described in terms of exciton states^{11,20}, absorb maximally at 390 nm. This corresponds exactly to the 390 nm band in the native shell and suggests the assignment of this band to the yellow protein *in situ* in which exciton interactions have also been found, although

after isolation and purification, absorption shifts to 410 nm (refs 2,7,9). Assuming a simple exciton model^{21,22} for this species, a monomer absorption maximum at 490 nm and the allowed exciton state at 390 nm, one calculates the corresponding bathochromically shifted and less allowed exciton state to be at 660 nm. Indeed, the absorption spectrum of purified yellow protein² clearly shows absorption by the less allowed transition in this region. Thus, the anisotropic distribution of bathochromically shifted excited states is such that the lowest energy level, the bathochromically shifted exciton state, is in the interior of the endocuticle. This assignment of an interior location to the yellow protein is in contrast to the recent suggestion based on resonance Raman scattering that it is at the shell surface⁹.

A quantitative description of the location of the various carotenoproteins may be obtained from measurements of the phase shift as a function of ω , provided α is known^{16,17}. In the present study, a qualitative estimation of depth is given by μ which ranges from 10 μm at 326 Hz to 35 μm at 26 Hz, if α is taken as 0.001 cm^2s^{-1} . This value of α is typical of biological materials²³ similar to chitin and yields values of μ in excellent agreement with the observed thickness of the epicuticle and depth of the pigmented zone¹⁹.

Although the work described here is structural in that it reports only the detection of a variety of carotenoprotein species and their organisation in the lobster shell, several interpretations are possible. The anisotropic arrangement of the pigments may not serve any photobiological role and may simply be a consequence of the ordered synthesis of the pigmented zone during moulting. Functions such as cryptic coloration may or may not be a property of the distribution of the pigments in layers. However, two possible functions which are dependent on pigment arrangement may be suggested. First, with different receptors serving specific layers of pigment a form of colour discrimination is obtained which could be important in a variety of photobiological processes. Second, pigments arranged with the lowest excited state in the interior could function as an antenna which absorbs light throughout the visible range and transfers excitation energy vectorially to the interior of the endocuticle where receptor sites may be located.

T.A.M. acknowledges a grant from the Faculty Grant-in-Aid program at Arizona State University. Also, we acknowledge the Donors of the Petroleum Research Fund, administered by the American Chemical Society and Research Corporation for support of this research. We thank D. Mackay for initial work on the spectrometer and F. Davis for continuing design and technical assistance.

 INSERM CONFERENCES INSERM CONFERENCES INSERM CONFERENCES INSERM CONFERENCES INSERM CONFERENCES INSERM

The French Institute of Health and Medical Research (Institut National de la Santé et de la Recherche Médicale) is organizing a series of meetings on advanced research topics in various biomedical fields. The meetings which started two years ago, are known as the INSERM CONFERENCES.

The aims of the conferences are :

- to foster the exchange of ideas, to evaluate new methods and new lines of investigation ;
 - to bring together scientists, mostly from European countries, working in universities and public or private research institutions.
- The meetings will be held under the direct responsibility of a chairman and a co-chairman.

The INSERM CONFERENCES have the following special features :

- only highly topical subjects are dealt with ;
- if possible, the data presented should not have been the subject of any earlier complete publication, a condition which therefore excludes general reviews ;
- the Conferences do not publish proceedings or any other material, even in a summarized form.

The chairman of each INSERM Conference will invite 15 to 20 scientists to give a report in line with the above conditions. The number of contributions will be limited to three or four per session and, at the discretion of the chairman, at least one third of the time will be given over to discussion and brief informal communications.

In addition to the invited speakers, at least fifty participants will attend the meeting, and efforts will be made to select young scientists. Experienced research workers from fields other than those relating to the Conference will also be welcome to attend. Participants will be chosen in such a way as to enable those engaged in all types of scientific research to establish personal contacts, exchange information and find new ways of working together.

PRACTICAL ARRANGEMENTS

The INSERM CONFERENCES 1979 will be held at the Domaine de Seillac, near Blois (180 km from Paris), during the months of September and October 1979 (full address : Domaine de Seillac, 41150 Seillac, France). Each conference will last three and a half days, from Sunday evening (departure from Paris) to Thursday afternoon. Working sessions will be held from 9 a.m. to 12.30 p.m. and from 5.30 p.m. to 8 p.m. On free afternoons, participants will have a wide choice of leisure activities at the Domaine de Seillac and in the surrounding area (Tennis, Table-tennis, bicycling, visit to the Castles of the Loire).

REGISTRATION FEE

Participants whose applications are accepted but who are not invited speakers, will be asked to pay their registration fee and board (1000 FF).

Scientists wishing to attend one of these three conferences have to submit this application form BEFORE JUNE 6th to INSERM Conferences, 101, rue de Tolbiac - 75645 PARIS CEDEX 13, France - Telephone : 584 14-41.

PRELIMINARY PROGRAM FOR 1979

SOMATIC GENETICS

GENE TRANSFER AND FUNCTIONAL ANALYSIS IN SOMATIC CELLS - September 23-27
François JACOB, Chairman ; Boris EPHRUSSI and Gérard BUTTIN, co-chairmen

The Conference will deal with three main topics :

- mechanisms of gene transfer
- genetic and epigenetic variation
- lymphocyte hybridomas (the genetic system and its applications)

The list of speakers includes :

R. AXEL	(New York)	D. PATTERSON	(Denver)
D. BOOTSMA	(Rotterdam)	G. PONTECORVO	(Londres)
S. BRENNER	(Cambridge)	K. RAJEWSKI	(Cologne)
R. CASSINGENA	(Villejuif)	N. RINGERTZ	(Stockholm)
M. GEFTER	(Cambridge U.S.A.)	F. RUDDLE	(New Haven)
J. JAMI	(Paris)	R. SCHIMKE	(Stanford)
R. KEMLER	(Paris)	L. SIMINOVITCH	(Toronto)
G. KOHLER	(Bâle)	E. SOLOMON	(Oxford)
C. MILSTEIN	(Cambridge)	M. WEISS	(Gif-sur-Yvette)
M. NABHOLZ	(Epalinges)	K. WILLECKE	(Essen)

IMMUNOLOGY

B CELL DIFFERENTIATION AND IDIOTYPES - October 1-4
M. SELIGMANN, chairman ; M.D. COOPER, co-chairman.

Session 1 : **Ontogeny and B cell differentiation**

Speakers : A. COUTINHO (Basel), Nicole LE DOUARIN (Nogent-sur-Marne), P. KINCADE (Rye), F. MELCHERS (

Session 2 : **Immunoglobulin genes and their expression**

Speakers : Ph. LEDER (Bethesda), T.H. RABBITS (Cambridge), F. ROUGEON (Paris), I. SCHECHTER (Rei

Session 3 : **Immunoglobulin receptors and secreted antibody products**

Speakers : S. AVRAMEAS (Paris), D. GIVOL (Rehovot), P. LIACOPOULOS (Paris),
M. PARKHOUSE (London), P. VASSALLI (Genève)

SCIENTIFIC INTEREST to be used for consideration of your request by the Scientific Conference Committee

DO NOT ENCLOSE PRE-PAYMENT WITH THIS APPLICATION FORM

Session 4 : Regulation of B-cell differentiation**Speakers :** C. BONA (Paris), G. MÖLLER (Stockholm), B. PERNIS (New York), E. UNANUE (Easton)**Session 5 : Human and experimental models of defective B-cell differentiation****Speakers :** M.D. COOPER (Birmingham, USA), H.G. KUNKEL (New York), W. PAUL (Bethesda), J.L. PREUD'HOMME (Paris)**Session 6 : Heterogeneity of Idiotypes and of anti-Idiotypic repertoire****Speakers :** P.A. CAZENAVE (Paris), M. FOUGEREAU (Marseille), O. MÄKELÄ (Helsinki), A. NISONOFF (Boston), J. URBAIN (Brussels)**Sessions 7 : Idiotypes and regulation of immune response (with emphasis on T cell idiotypic determinants)****Speakers :** K. EICHMANN (Heidelberg), K. RAJEWSKY (Köln), B. RUBIN (Copenhagen and Marseille), H. WIGZELL (Uppsala), D. WILSON (Philadelphia).**GENETIC CONTROL AND DISEASES - October 7-11****Jean ROSA, chairman ; André BOUE, co-chairman.**

The conference will deal with three main topics :

MOLECULAR ASPECTS OF GENETIC DISEASES :

Y. BEUZARD	(Créteil)	J. OLD	(Oxford)
J. CLEGG	(Oxford)	S. OTTOLENGHI	(Milano)
J. GODDET	(Villeurbanne)	G. STAMATOYANNOPOULOS	(Seattle)
Y. KAN	(San Francisco)	U. TESTA	(Créteil)
P. LITTLE	(London)	D. WEATHERHALL	(Oxford)
U. MAZZA	(Torino)	R. WILLIAMSON	(London)
A. NIENHUIS	(Bethesda)	W.G. WOOD	(Oxford)

POLYMORPHISM AND GENETICALLY DETERMINED DISEASES :

D. BOOTSMA	(Rotterdam)	D. ROBINSON	(London)
J.C. DREYFUS	(Paris)	Y. SVENNERHOLM	(Goteborg)
M. FERGUSON	(Glasgow)	K. VON FIGURA	(Munster)
H. GALJAARD	(Rotterdam)	V. WOLF	(Erlburg)
B. HOPKINSON	(London)		

GENETIC CONTROL AND MALIGNANT CELLS :

R. CASSINGENA	(Villejuif)	D. STEHELIN	(Lille)
R. JAENISCH	(Hamburg)	P. TAMBOURIN	(Orsay)
J. JAMI	(Paris)	K. WILLECKE	(Essen)
V.E. PAPAIOANNOU	(Oxford)

APPOINTMENTS VACANT

Basic Grade Physicist

required for Pilgrim (District General) Hospital,
Boston, Lincolnshire.

to assist the Head of the Unit in establishing Patient Services within the hospital and the South Lincolnshire Health District.

This new Department which is an integral part of the Lincolnshire Area Medical Physics Service, already provides Patient Services in Diagnostic Ultrasound and Physiological Measurements, including Audiology and a Nuclear Medicine Service is about to be inaugurated.

The Department is presently equipped with:—

Ultrasound:	Pickler 80L, Kretz
Physiological Measurements:	Medelec
Nuclear Medicine:	Cleon LFOV/Data Processor
Electronics:	Basic Test equipment.

Applicants should possess a B.Sc in Physical Sciences and, preferably, experience in either Ultrasound or Nuclear Medicine. The appointee will be able to pursue appropriate training and it is anticipated that he/she will eventually assume responsibility for one of the major aspects of the Department's functions.

Boston is a pleasant port and market town in rural surroundings and within easy reach of East Midland centres and East Coast Resorts. Housing is relatively inexpensive.

For Application form contact the District Personnel Department, South District Offices, South End, Boston, Lincs., Tel: Boston 66505.

Closing date for receipt of completed applications May 14, 1979.

(578)A

Lincolnshire Area Health Authority - South District

UNIVERSITY OF SINGAPORE MATHEMATICS

Applications are invited for teaching appointments, ranging from Lectureships to Senior Lectureships, in the Department of Mathematics. Candidates with a Ph.D. degree and with special qualifications in numerical analysis and/or operations research and able to teach computer science are preferred. The basic monthly salary for the two levels of appointment are as follows: Lecturer—\$51,445 to \$52,615; Senior Lecturer—\$52,485 to \$53,265 (US\$1.00 equals S\$2.18). The initial salary will depend on the candidate's qualifications and experience and level of appointment offered. In addition, the University pays a 13th month annual allowance of one month's salary in December of each year. Leave, medical and provident fund benefits are available. The University at present contributes to the staff member's provident fund at the rate of 16½ per cent of his monthly salary. Subsidised housing will also be provided at current rentals ranging from S\$100 to S\$350. Candidates should write to: The Registrar, University of Singapore, Kent Ridge, Singapore 5, giving curriculum vitae (bio-data), with full personal particulars and also the names and addresses of three referees.

573(A)

THE OPEN UNIVERSITY Faculty of Science

Lectureship in Organic Chemistry

The preparation of Open University courses involves writing course text and assessment materials, making television and radio programmes, devising home experiments and planning and participating in summer school activities. Applicants should have a keen interest in teaching and should be willing to experiment with the media available. The successful candidate will hold a higher degree in Organic Chemistry, and will be expected to maintain an active interest in research. The appointment will be available from September, 1979. Salary will be within the lecturer grade £3,883—£7,754 p.a. (under review). Annual holiday entitlement is 30 days, and two months' study leave per year is available for an approved purpose. Application forms and further particulars are available, by postcard request please, from The Recruitment Office (JD2270/2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404; there is a 24 hour answering service on 63868. Closing date for applications: 15th May, 526 (A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London) Denmark Hill, London SE5 8RX DEPARTMENT OF CHILD HEALTH SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

Applications are invited for the above post from candidates with considerable experience of laboratory practice and management gained preferably in a Medical School, University or similar environment.

In addition to the investment in and suspension of technical aspects of routine procedures and a variety of research projects, the person appointed will be expected to be in charge of the administration of the laboratories, to involve ordering equipment and supplies and the responsibility for appropriate departmental grants. The department is housed in a modern building and has well equipped laboratories, and many research projects are being carried out, especially into the diseases, physiology and nutrition of newborn babies.

Salary on the scale £4,347 to £5,769 plus £354 London Weighting (under review) according to qualifications and experience.

Applications, giving full curriculum vitae and the names and addresses of two referees should be sent to the Secretary of the Medical School from whom further details may be obtained (telephone: 01-274 6222 Ext. 2040). Closing date: May 11, 1979. 516(A)

UNIVERSITY OF THE SOUTH PACIFIC Applications are invited for the post of SENIOR LECTURER/ LECTURER IN EDUCATION

(Post 79/37). The appointee is expected to assume major responsibility in the teaching of Science/Mathematics curriculum courses at the diploma and degree teacher education programmes of the School, and to assist with school experience supervision, i.e. student teaching. He/she will be expected to assist in other Education courses in one of the areas of the Foundations of Education. The applicant is expected to have relevant postgraduate qualifications in either Science or Mathematics education. Relevant qualifications in one of the areas of the Foundations of Education particularly in the sociology, philosophy, or history of education will be advantageous. Some relevant teaching experience in both secondary and tertiary settings will be an added asset. The appointee is expected to assume post by July 1979. Salary scales Senior Lecturer: F\$11,960 to F\$14,130 p.a. Lecturer: F\$8,175 to F\$11,563 p.a. (£1 sterling=F\$1.75). The British Government may supplement salaries: in range £1,842 to £2,796 p.a. (sterling for married appointee and £444 to £1,164 p.a. (sterling) for single appointee (currently under review and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages: 15% gratuity; superannuation scheme appointment allowance; partly furnished accommodation at 12½% of salary—under review; contract for 3 years. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of the South Pacific, PO Box 1168, Suva, Fiji by May 31, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address. 528(A)

ENHANCED OIL RECOVERY RESEARCH AT IMPERIAL COLLEGE

Applications are invited for two Postdoctoral Research posts (S.R.C. sponsored) tenable for up to three years for the study of:

1. The behaviour of emulsions in reservoir rocks.
2. Capillary effects in the enhanced recovery of oil from reservoir rocks.

The work is of fundamental importance to oil recovery processes and requires an appreciation of fluid-surface interfacial phenomena and of porous media.

The usual S.R.C. conditions apply, with a starting salary within the range of research and analogous staff, Grade 1A, £3,883 to £6,555 (under review) plus £502 L.A. and the posts carry U.S.S. benefits. Initial placing dependent on age, qualifications and experience.

Enquiries and applications (giving curriculum vitae and the names of two referees) to Dr R. A. Dawe, Mineral Resources Engineering Department, Imperial College, London SW7 2BP. A number of Studentships for study to Ph.D. are also available. 592(A)

THE OPEN UNIVERSITY

Faculty of Science

BIOLOGY HISTOLOGY TECHNICIAN

(£3,222—£3,708)

We require an experienced Technician to take responsibility for organising and providing an histology service within the discipline. It is hoped that the post will also provide some photographic support. Ref: 3786.

BIOLOGY RESEARCH TECHNICIAN

(£3,222—£3,708)

Professor Steven Rose requires an experienced Technician to take responsibility for the day to day organisation of the Brain Research Group's main Biochemical Laboratory, and for assisting in various research projects. Ref: 3787

BIOLOGY RESEARCH TECHNICIAN

(£3,984—£4,758)

Dr. Geoff Eimon requires an experienced Technician to assist his research into the visual system. The Technician will assume responsibility for the day to day organisation of his laboratory which is currently using electrophysiological recording and histological procedures to investigate visual projections in the avian fore brain. Ref: 447.

The Campus is within the new city of Milton Keynes which has ample housing available for rent or purchase. The University offers generous assistance with relocation expenses.

Application forms and further particulars are available from The Recruitment Office (JD3786/1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 8AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868.

Please quote reference number of the post in which you are interested.

Closing date for applications: May 4.

521(A)

UNIVERSITY OF PAPUA
NEW GUINEA
(PORT MORESBY)

Applications are invited for the position of

LECTURER/
SENIOR LECTURER
IN AGRONOMY

in the DEPARTMENT OF AGRICULTURE. Applicants should have a good first degree in Agriculture with post-graduate experience in Agronomy, preferably at the Ph.D. level. Preference will be given to applicants with university teaching and research experience in tropical agriculture. The appointee will be responsible for courses in the agronomy of plantation crops and pasture, up to honours degree level and may be required to assist in other courses according to experience and interests. He/she will be expected to supervise postgraduate students and to carry out independent research. The appointee may also be asked to assist with agronomic projects on the departmental farm and undertake other relevant duties as may be assigned from time to time. Currently the department is split between Port Moresby and Lae, but from February 1981 will be unified in Port Moresby. The appointee may be asked to teach one or two semesters in Lae initially but in the long term will teach full time in Port Moresby. Salary scales: Senior Lecturer K15,150 p.a. Lecturer K13,300 p.a. (21 sterling=K1.49). Family passages, 3 year contract, gratuity of 24% of salary, of which 5% is taxable, research allowance, baggage allowance, overseas leave. Detailed applications (2 copies) with recent small photograph with curriculum vitae and naming 3 referees to be sent direct to Secretary, Box 4820, University PO, Papua New Guinea by May 25, 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address 530(A)

AMGUEDDFA
GENEDLAETHOL CYMRU
NATIONAL MUSEUM
OF WALES
APPOINTMENT OF
PRINCIPAL OFFICER,
Oriol Eryri,
The Environmental Centre,
Llanberis, Gwynedd

Applications are invited for the post of Principal Officer at Oriol Eryri, the environmental gallery at Llanberis, Gwynedd.

The gallery, which is to be the first major outstation of the National Museum in North Wales is currently being built and will be opened to the public in 1982.

It will, in essence, be an outstation of the Departments of the earth and biological sciences at the Museum and will complement the work currently being carried out at the North Wales Quarrying Museum and at the Roman Fort Museum at Segontium, which are respectively outstations of the Welsh Industrial and Maritime Museum and the Archaeology Department.

The centre will contain an interpretative gallery illustrating the relationship of man and his environment in North West Wales, an exhibition gallery with facilities for displaying works of art, laboratories, lecture rooms and a general purpose hall which will be available for use in the evenings by local people.

Candidates must have a degree either in the earth or biological sciences and preferably have some experience in Museum work including administration. They should have the ability to make contact with both the general public and scholars.

A knowledge of Welsh is essential. Contributory pension rights. Salary scale £5,717 to £8,856 (under review).

Further particulars may be obtained from the Secretary, National Museum of Wales, Cardiff CF1 3NP, to whom applications should be submitted not later than Tuesday, May 31, 1979. 559(A)

UNIVERSITY OF MAINE

With the establishment of the Center for Marine Studies, the University of Maine is placing priority emphasis on the development of a strong, competitive research and graduate education program in marine resources. Nominations and applications are invited for the following positions.

CHAIRPERSON
DEPARTMENT OF OCEANOGRAPHY

The Oceanography Department, a graduate department offering M.S. and Ph.D. degrees, is primarily housed at the University's marine laboratory at Walpole, Maine. It currently has a faculty of 8. Present research activities include ecology of sub-boreal estuarine organisms, environmental biology and geochemistry, aquaculture and geological oceanography.

Responsibilities:

to serve as chief administrative officer; and develop a coordinated research program in physico-chemical estuarine processes.

Qualifications:

- (1) innovative leadership and administrative capability,
- (2) continuing scholarly achievements,
- (3) evidence of consistent success in funded research,
- (4) earned doctorate.

Academic appointment as Associate or Professor, tenure track. Salary open within University constraints.

FISHERIES POPULATION DYNAMACIST
DEPARTMENT OF ZOOLOGY

The Zoology Department, with a current faculty of 18 is primarily housed on the Orono campus, and includes the Cooperative Fisheries Unit. Ten of the faculty have research interests in marine or freshwater biology.

Responsibilities:

to develop a graduate education and research program on population dynamics of fishes.

Qualifications:

- (1) earned doctorate,
- (2) additional professional experience in marine fisheries biology desirable.

Academic appointment as Assistant Professor, initially one year with probability of additional 2-4 year University commitment.

MIGRATORY FISH BIOLOGIST
MIGRATORY FISH RESEARCH INSTITUTE

The Migratory Fish Research Institute is an interdisciplinary group of primarily Zoology faculty whose research interests focus on the biology of migratory fishes.

Responsibilities:

to collaborate in research on oceanic and estuarine migrations of larval and juvenile seas, and to assist in research proposal development.

Qualifications:

- (1) earned doctorate,
- (2) training and experience in fish migration and orientation preferred, and,
- (3) marine background or orientation.

Research appointment, initially one year with probability of second year continuation and possibility of third year depending on extramural program funding.

MARINE STATION
ADMINISTRATIVE OFFICER

The Ira C. Daring Center is the marine laboratory of the University of Maine. It is located on a 152 acre site on the Damariscotta estuary and includes Lowe's Cove. The facility comprises 10,000 square feet of laboratory and teaching space, including an Aquaculture Center, a developing conference center, a library, dockside facilities, and a fleet of small vessels.

Responsibilities:

to serve as the Chief Administration officer of a semi-isolated marine facility in support of educational and research programs, to be responsible for budget development and control, and for an expanding promotional/developmental activity.

Qualifications:

- (1) extensive administrative experience,
- (2) evidence of ability to communicate effectively with the public; and,
- (3) experience in sea-oriented organization including logistics, desirable.

Salary \$16,000 to \$18,000

Applicants should send complete resumes, samples of publications, and names of three referees, by May 15, 1979, to

Secretary, Search Committee
Center for Marine Studies
Room 14, Coburn Hall
University of Maine at Orono
Orono, ME 04468 U.S.A.

The University of Maine is an Equal Opportunity/Affirmative Action Employer. W70(A)

ENVIRONMENTAL TECHNOLOGY DEPARTMENT

Applied Statistician/Biometrician: M Sc, Ph D, to teach basic statistics applied to biology, ecology and medicine

Analytical Chemist: M S., Ph D, Teaching and practical experience in general analytical and instrumental methods, or experience in water or environmental analysis.

Environmentalist: M.S., Ph.D., in environmental studies and geographical aspects Teaching and practical experience required

Ecologist: M S, Ph D, Experience in warm climates preferred Interest in field work is essential

Environmental Engineer: M Sc., Ph D., or Engineering Degree. To teach environmental engineering relevant to a developing country. Teaching and practical experience in "warm" climates is an advantage

Technologists, Technicians/Demonstrators:

- 1 With degree or extensive experience in preparing and teaching ecology laboratory practicals Knowledge of electronics is helpful
- 2 Experience in analytical chemistry and instrumental methods of analysis Environmental Microbiologist with Water, Soil and Air analysis experience.

Medical Technology Department

Hematologist - Serologist: M.S, Ph D or Certified Medical Technologist To teach Hematology and Serology. Teaching and practical experience desired.

Demonstrators, Technologists, Technicians: For teaching laboratory in Biochemistry, Clinical Chemistry, Hematology and Medical Microbiology

Food Technology Department Lecturers

Food Analytical Chemist: M Sc, or Ph D with teaching and practical works experience

Food Nutritionist: B Sc, or M Sc., with teaching and laboratory experience

Technologist/Demonstrator and 2 Technicians: B Sc /HND or equivalent qualifications for laboratory demonstration

All applicants must be fluent in spoken English, the language of instruction. Appointments depend on qualifications of appointees. No age limit exists on applicants. Fringe benefits include free air conditioned housing, medical services, transportation and terminal gratuity

Applications should be addressed to
The Dean
Higher Institute of Technology
Lyster Campus, Hal-Far, Malta.

LIFE SCIENTISTS A support Role in Agricultural Research

The successful candidates will join teams concerned with investigational and development work, and advising farmers.

Vacancies will probably be in the following locations. ANALYTICAL CHEMISTS—Newcastle and Wye; ENTOMOLOGISTS—Cambridge, Evesham, Leeds, Reading and Wye; MICROBIOLOGISTS—Newcastle, Reading and Wye; PLANT PATHOLOGISTS—Evesham, Newcastle or Wye; SOIL SCIENTISTS—Newcastle, Starcross and Wolverhampton.

Candidates (normally aged under 27) must have (or expect to obtain in 1979) a degree, HND, HNC or an equivalent qualification in an appropriate scientific subject. Relevant experience an advantage.

Salary. £2,555 to £4,415 Starting salary may be above minimum Non-contributory pension scheme Promotion prospects.

For further details and an application form (to be returned by 21st May, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB; or telephone Basingstoke (0256) 68551 (answering service operates outside office hours) Please quote ref. S/5130.

MAFF — Agricultural Development and Advisory Service

55

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GENETICS LECTURESHIP

Applications are invited for the post of Lecturer in Genetics. Candidates with qualifications in any field of Genetics will be considered, but preference will be given to candidates with experience in both pre- and post-doctoral levels in the field of molecular genetics.

Salary will be on the scale £3,883 to £7,754 (under review), plus superannuation.

Further particulars are available from the Assistant Registrar (Science and Engineering), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) including curriculum vitae and naming three referees, should be sent by Monday May 14, 1979.

Please quote ref NL6 541(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF PHYSICS

Applications are invited for the post of University Demonstrator in the above Department. Teaching duties (laboratory and tutorial work) will not normally exceed 10 hours per week. The successful candidate will be expected to take part in the research programme of the Department and to register for a higher degree, if he/she does not already hold one. Details of research can be obtained on application to the Department.

Salary in accordance with experience and qualifications, between £3,384 and £4,882 per annum without a Ph D degree and between £3,883 and £5,600 with a Ph D degree. The appointment is for three years, and will commence on October 1st, 1979.

Applications by letter, including a curriculum vitae and the names of two referees, should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh, EH8 9YL, not later than July 22nd. Please quote reference 1040.

PUBLIC HEALTH LABORATORY SERVICE BOARD

Centre for Applied Microbiology and Research, Porton Down
Genetic Manipulation Laboratory

Applications are invited for scientists with enthusiasm and ability to join the Genetic Manipulation Laboratory, within the Centre for Applied Microbiology and Research, Porton Down.

- 1 Senior/Basic Grade Microbiologist to join a small research team working on the development and practical uses of genetic manipulation techniques. The successful applicant will be expected to take part in the on-going research programme and to initiate independent research in related areas. Some work will take place under conditions of containment and appropriate training will be given where necessary. Applicants should have a Ph D acceptable equivalent and practical knowledge of genetic manipulation.
- 2 Medical Laboratory Scientist Officer to assist in the work of the genetic manipulation laboratory. Applicants should have a BSc HNC and familiarity with techniques employed in molecular biology would be highly desirable. NHS Terms and Conditions of Service. Annual salaries will be according to age and experience. The following scales: Senior Microbiologist, £5,451 to £6,837; Grade Microbiologist, £2,991 to £3,261 to £4,680.

Further details of the above can be obtained from Mrs M I at PHLS CAMR, Porton Down, Wiltshire, to whom applications with full career details, qualifications and names and addresses of referees should be submitted by 11 May 11, 1979. The director of the laboratory, Dr P Greenaway, will be pleased to discuss the posts with interested candidates. SC

Birds Mammals Agriculture

These posts are in the Land Pests and Bird Research Department which undertakes ecological, biological and pathological studies with a view to controlling harmful birds and mammals. There are excellent library and experimental facilities.

Vertebrate Ecologist

... to develop and test the potential of new methods of rabbit control, e.g. poison baiting. This will involve selecting test sites and studying the social behaviour and feeding habits of rabbits. In addition, the ecologist will be responsible for evaluating the extent of crop damage caused by rabbits and assessing the effectiveness of new control methods.

Candidates, normally aged under 30, should have a good honours degree or equivalent and at least 2 years' relevant postgraduate experience, ideally in vertebrate ecology or animal behaviour. Appointment as Higher Scientific Officer.

Ethologist

... to lead a small team studying the foraging strategies and food preferences of birds, particularly bullfinches, under natural conditions with a view to developing repellants for use in crop protection. This will involve planning and carrying out aviary and field experiments and publishing results.

Candidates, normally aged under 30, should have a good honours degree or equivalent in an appropriate discipline. At least 2 years' postgraduate experience in the study of animal behaviour and a sound knowledge of statistical methods is essential. An interest in optimal foraging theories and experience of working with birds is highly desirable. Appointment as Higher Scientific Officer.

Ornithologist/Ecologist

... to initiate a study of the relationship between the roosting and feeding habits of starlings in agricultural habitats. The work will also involve analysing the factors that may influence the selection of feeding grounds, assessing the profitability of producing cheap alternative food for starlings in an attempt to reduce damage to economically important crops, investigating breeding control methods and preparing results for publication.

Candidates, normally aged under 27, should have a good honours degree or equivalent in an appropriate discipline. *Final year students may apply.* Appointment as Scientific Officer.

Ornithologist

... to join a small team studying the behaviour of birds in airfield environments and advising on the potential danger to aircraft. The work will involve collecting and analysing data on populations and movements of lapwings whose affinity for airfields by both day and night is well established but little understood. In addition, the successful candidate will improve methods to alleviate bird hazards, advise civil and military aviation authorities on ornithological problems and instruct airfield personnel on bird control techniques.

Candidates, normally aged under 27, should have an honours degree or equivalent in an appropriate discipline. *Final year students may apply.* Appointment as Scientific Officer.

Salary for Higher Scientific Officer ranges between £4,100 and £5,450 and for Scientific Officer between £2,840 and £4,410. *Salaries under review.* Promotion prospects. Non-contributory pension scheme.

Men and women may apply. For further details and an application form (to be returned by 21 May, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref. SB/40/AF.* Agricultural Science Service Worplesdon Laboratory, Surrey 589(A)

Group**
CIVIL SERVICE

THE UNIVERSITY OF SHEFFIELD RESEARCH IN INFORMATION SCIENCE Information Science Studentships and Postdoctoral Fellowships

Applications are invited from well-qualified graduates for consideration for the award of research studentships and postdoctoral fellowships for research in information science.

Candidates for studentships should normally have, or expect to obtain by October 1979, at least an upper (or equivalent undivided) second class honours degree in science or technology. Candidates for fellowships should hold, or expect to be awarded by October 1979, a Ph.D. in science or technology. Conditions of award will be similar to those applied by the S.R.C. including the usual British citizenship and residence requirements.

Current research in the School includes studies of computer-based information storage and retrieval systems, application of information theory in information systems, user studies in all disciplines, national information system design, information services in local authority social services departments as well as work on computer-based chemical information storage and retrieval systems.

Applications should be submitted to Professor M. F. Lynch, Chairman, Postgraduate School of Librarianship and Information Science, by May 25, 1979. Quote ref: R 288/G. 556(A)

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE RESEARCH OFFICER

The Director's research programme is primarily concerned with an evaluation of the advantages which accrue from the use in research of specific pathogen free animals, in particular the cat. A person in the Research Officer category is required to assist the Director in this programme. Opportunities will occur for collaborative work with other departments in the Centre, which cover the whole spectrum of Laboratory animal science.

The Successful applicant will have a degree or equivalent in a biological science, and at least two years relevant research experience. Salary will be related to age, qualification and experience and is supplemented by £354 London Weighting. Contributory pension scheme.

Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to The Director, MRC Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF. 561(A)

MRC

Medical Research Council

Leeds POLYTECHNIC

School of Health and Applied Sciences LECTURER II IN NUTRITION AND DIETETICS (NEW POST)

Applications are invited from State Registered Dietitians having some community and/or clinical experience, to join a young and enthusiastic team concerned with the teaching of Nutrition and Dietetics to Degree and Diploma students in a well established school.

Salary Scale: £4,101 to £6,558.

Details from:

The Services Officer (ND/30), Leeds Polytechnic, Calverley Street, Leeds LS1 3HE. Tel: 0532 462355.

Informal enquiries may be made to Dr K. R. Fell, Head of School. Tel: 0532 462941.

Closing Date: May 21, 1979. Please enclose s.a.c.

577(A)

International Co-Ordinator Diagnostics

World wide expansion of Biodata Diagnostics has resulted in the need for a scientist who will co-ordinate and direct the activities of Biodata at international level.

The person appointed will be expected to assume overall accountability for R & D, quality control, production and world wide strategy for the marketing and profitability of Biodata Diagnostics.

Applicants should possess a postdoctoral degree together with wide experience in radio-immunoassay, enzyme immunoassay based diagnostics, together with the ability to lead a multi-national team of scientists.

Though based in the U.K. (Hertfordshire), the position will involve frequent visits to Companies and laboratories within the Group in Germany, Israel, Italy, Switzerland, North and South America.

Reporting directly to the Group's Chairman in Geneva this appointment presents a unique opportunity in developing the existing range of diagnostics and opening up new areas through internal R & D, and/or acquisition of products, techniques or Companies. An ability to communicate and negotiate at the very highest level with scientists and commercial groups throughout the world is essential.

Remuneration and fringe benefits are commensurate with this important international appointment.

Candidates should write, enclosing a comprehensive C.V., and marking the envelope "STRICTLY CONFIDENTIAL" to:

Dr L. Margarito,
Sero Laboratories (U.K.) Ltd.,
Beesmer Road,
Welwyn Garden City,
Hertfordshire, AL7 1HH.

SCIENTISTS

required for the
Institute of Meteorology and Arid Land Studies
King Abdul Aziz University, Saudi Arabia

Scientists at all ranks are needed in the following departments:

- 1) Meteorology Department
- 2) Arid Land Studies Department
- 3) Hydrology and Water Shed Management Department

Our pay scales are attractive and furnished housing is provided. Two months leave for the candidate and family is given with round trip air travel tickets (4 maximum) between Jeddah and his home town.

Send your applications as soon as possible by air mail and have two letters of reference sent directly to:

Dr. Fawaz Alamy, Dean, Institute of Meteorology and Arid Lands Studies,
King Abdul Aziz University, P.O. Box 1540, Jeddah, Saudi Arabia. 581(A)

UNIVERSITY OF BRISTOL

Applications are invited for post of

LECTURER IN ANATOMY

A vacancy exists for a lecturer with a primary responsibility to the teaching of medical students. As a being responsible for the teaching gross anatomy to medical, veterinary and science student Department offers courses in anatomy, endocrinology, reproductive embryology, dental anatomy, physical anthropology, with special teaching in each of these topics Honours degree level.

The Department has excellent facilities for research and is pre-organised into a number of research groups working in the following: biochemistry and physiology of secreting neurones, neuroanatomical dopamine pathways, electrophysiology of the CNS, control of parturition, bone mechanics, tooth eruption physical anthropology.

Salary will be on the scale £3, £7,754 (under review) and letter application including the name addresses of three referees should be sent to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TD, before May 1979 (quoting ref TLJ). Late persons are welcome to visit Department by arrangement with Head of the Department's secretary (Tel: 0272-24161, Ext 367) 55.

UNIVERSITY OF MELBOURNE

LECTURESHP/

SENIOR LECTURESHP

in the

DEPARTMENT OF ANATOMY

With the development of new research and teaching initiatives in the Department of Anatomy, applications are invited for a position as Lecturer or Senior Lecturer in Anatomy. Applicants should have considerable research experience in one of the following fields: cell biology/histology, neurosciences, or topographical anatomy. Teaching experience would be a advantage.

The Department is well provided with transmission and scanning electron microscopes and ancillary equipment. Technical assistance is available. Participation in interdisciplinary research is actively encouraged.

Salary: Lecturer — \$A15,782 to \$24,687 p.a. In addition, a special loading of \$A2,500 p.a. is payable to a medically qualified appointee.

Additional details may be obtained from Professor G.B. Ryan in the University.

Further information regarding application procedure and conditions of appointment is available from Staff Officer, University of Melbourne, Parkville, Victoria, Australia 3010, from the Association of Commonwealth Universities (Appts), 36 G Square, London WC1H 0PP. Applications close on June 8, 1979.

527

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) POSTDOCTORAL RESEARCH SCIENTIST

An experienced postdoctoral research scientist is required to join a Group funded by the Cancer Research Campaign and based at the Cancer Institute of Biochemistry in The Middlesex Hospital Medical School.

This Group is concerned with competing pathways of carcinogenesis, activation, inactivation and control of gene expression with macromolecular interactions. Particular attention is focused on: thione and interactions with branched and proteins both cytoplasmic and nuclear.

The possibility of tenure for post is under consideration.

Applicants should write to Dr Ketterer, Courtauld Institute of Chemistry, The Middlesex Hospital Medical School, London W1P 7P 522

Biological Assessment of Medical Products

c. £55000/£60000

The Radiochemical Centre Limited is a world leader in the development and manufacture of a range of radioactive products. Group sales are £32m. per annum and the company has been growing at more than 20% each year. Expansion has occurred in each part of the business and particularly in the development of medical products.

This is a new post for an additional professional scientist to assist with the development of new radiopharmaceuticals for in vivo diagnostic applications. This work will involve close co-operation with project leaders, often chemists, in setting up and supervising screening protocols for speculative products, more detailed testing procedures for identified products and collation of biological data for presentation to drug regulatory authorities. The job holder will play a part in identifying new areas for work in the

Department and eventually take over leadership of certain projects.

Applicants should hold a good honours degree in a biological science and have undertaken post-graduate research to the level of Ph.D. in a paramedical or biological subject (Physiology, Pharmacology or Biochemistry would be good examples). Practical experience of in vivo biological experimentation is also necessary, as is the ability to communicate easily with other staff.

Starting salary will be around £5500/£6000 p.a. according to qualifications and experience. Conditions of employment are excellent and include assistance with re-location if appropriate.

Please write with comprehensive career details to: Dr. J. S. Allinson, Personnel Officer.

HARVARD UNIVERSITY FULL/ASSOCIATE PROFESSOR IN OBSERVATIONAL OPTICAL ASTRONOMY

The Department of Astronomy of Harvard University is seeking to fill a position in Observational Optical Astronomy either at the level of Full Professor with tenure or at the level of Associate Professor to be considered or tenure within three years. The appointment can commence on or after July 1980. In association with the Harvard College Observatory and the Smithsonian Astrophysical Observatory, the Department of Astronomy has access to optical observing facilities at the Agassiz Station in Massachusetts and at Mount Hopkins in Arizona. At Mount Hopkins the facilities include the Mautimirror Telescope which is jointly operated by the Smithsonian Astrophysical Observatory and the University of Arizona. Other active observational programs in progress in the Department include X-ray observations using the Einstein Observatory, VLBI observations using the Harvard Radio Astronomy Station in Fort Davis, Texas and balloon-borne infrared observations.

Expressions of interest, inquiries and applications are invited. Please write to the Chairman, Search Committee, Department of Astronomy, 60 Garden Street, Cambridge, Massachusetts 02138. Candidates must have substantial observing experience using either ground-based or space-borne instrumentation. We explicitly encourage applications from women and minority group candidates.

W82(A)

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE RESEARCH OFFICER

The Centre's Accreditation Department manages a national scheme concerned with monitoring the quality of laboratory animals of many species produced by commercial breeders and suppliers. The scheme aims to ensure that adequate standards of housing and husbandry are maintained; it acts as an information exchange on sources of supply; and it provides veterinary advice to the centre.

A vacancy in the Research Officer category exists in the department. The post holder will be expected to travel widely in Great Britain. Applications are invited from persons with a degree or equivalent qualification in a biological science, and at least two years research experience. Salary will be related to age, qualification and experience and is supplemented by £354 London Weighting. Contributory pension scheme.

Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to The Director, MRC Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF.

The Research Division of Synthelabo located in
PARIS
requires a
SENIOR CARDIOVASCULAR PHARMACOLOGIST
to join its Department of Biology

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

For this key position in the Cardiovascular Group we require a professional and highly motivated scientist who will be responsible for various projects within the group and should also be able to conduct independent research programmes.

Applicants can be either male or female and should have relevant postdoctoral experience (a maximum of five years). It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent directly to:

"NATURE"
c/o Box No. W67(A) 3 DYERS BUILDINGS
HOLBORN, LONDON EC1N 2NR

W67(A)

ELSEVIER'S SCIENCE DIVISION

BIOCHEMICA ET BIOPHYSICA ACTA

Applications are invited for a post in the BBA EDITORIAL SECRETARIAT.

The BBA Editorial Secretariat, located in Amsterdam, is a small team of biochemists involved in the selection of manuscripts for publication in the world's largest biochemical journal. The work involves the choosing of reviewers for submitted articles, and subsequent correspondence with authors and editors, leading to eventual acceptance or rejection of the manuscripts. The Secretariat also maintains close contact with the journal sub-editing team, and advises on matters such as nomenclature and terminology. They thus play a central role in the quality control of the journal.

Candidates should meet the following requirements:

- a wide knowledge of the biochemical sciences
- 2-4 years of postgraduate research experience
- initiative, decisiveness, tact and an eye for detail
- an excellent command of the English language
- age under 30 and resident in Europe.

The job offers modern working conditions including excellent social services and a good salary and bonus system. Holidays amount to 24 working days per year, plus public holidays.

Applications, including curriculum vitae, should be addressed to the Personnel Department Elsevier's Science Division, P.O. Box 2400, 1000 CK Amsterdam, The Netherlands. W69(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

SCHOOL OF PHYSICAL AND MOLECULAR SCIENCES

Studies of
unstable molecules by
Infrared and Microwave
Spectroscopy.

Applications are invited for the S.R.C. supported post of Postdoctoral Research Officer to work in collaboration with Drs S. W. Charles, J. N. Macdonald and N. L. Owen on spectroscopic investigations of small acetylenic and ethylenic derivatives. Applicants should preferably have experience in either infrared or microwave spectroscopy of small molecules.

The appointment, which will be for one year in the first instance, will normally be renewable for a second year, and the preferred commencing date is October 1979. The starting salary will depend on age and experience, and will be in the range £3,883 to £4,382 per annum (under review).

Applications (two copies), giving details of qualifications and research experience, together with names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG. 502(A)

UNIVERSITY OF MANCHESTER LECTURER IN PHARMACOLOGY

Applications are invited from science and medical graduates for this post, tenable from October 1. Science graduates will normally be expected to have obtained a Ph.D. and to have some postdoctoral research experience as well as teaching experience in pharmacology. Salary range: £3,883 to £7,754 p.a. Superannuation. Further particulars and application forms (returnable by May 10 from the Registrar, The University, Manchester M13 9PL. Quote ref: 85/79/N. 337(A)

PHYSIOLOGIST/ PHYSIOLOGICAL ECOLOGIST

Applications and nominations are invited for a tenured professorship in the Department of Biology at Harvard University (although candidates at the non-tenured levels of assistant and associate professor will be considered). The position involves teaching and research in the field of whole plant physiology and/or physiological ecology. A specialist in photosynthesis or water relations is preferred, who will join an active and growing group of ecologists and population biologists in an academic environment.

Letters of application, with résumé and three references, should be sent by August 1, 1979, to:

Professor Peter S. Ashton,
Harvard University Herbaria
Building,
22 Divinity Avenue,
Cambridge, Massachusetts 02138.

An affirmative action/equal opportunity employer W79(A)

Manchester Area Health Authority (T) Central District SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER (or Senior Scientific Officer N.H.S.)

Required for the cellular immunology section of the Department of Medical Genetics. The work involves cellular matching in renal transplantation and research in the immunogenetics of human leukaemia. A desire to participate in research and a knowledge of immunology would be an advantage.

Send applications and the names of two referees to Dr R. Harris, Department of Medical Genetics, St. Mary's Hospital, Hatheridge Road, Manchester M13 0JH. 542(A)

UNIVERSITY COLLEGE
OF NORTH WALES,
BANGOR

RESEARCH ASSISTANT:
WOOD DEGRADATION

Applications are invited for the above post, in the College's Department of Forestry and Wood Science, to assist with the examination of water-soluble and their performance when added to wood. Applicants should be holding, or have, a good Honours degree in Chemistry, Physics, Wood Science/Wood Technology, or Materials Science, and have an interest in surface phenomena or in the use of wood as an industrial material.

The appointment is grant-funded, and will be for one year in the first instance, commencing October 1, 1979, with the possibility of extension for a further two years.

The appointment will be within the salary range: £3,384 to £3,883 per annum (under review).

Applications (two copies), giving details of age and qualifications, together with the names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained. Closing date for applications: May 1, 1979. 501(A)

LA TROBE UNIVERSITY
Melbourne, Australia
VISITING
FACULTY POSITION
IN
ORGANIC CHEMISTRY

The Department of Organic Chemistry wishes to appoint a visiting faculty member for a period of 6 months commencing about mid-February 1980. The successful applicant will undertake some undergraduate teaching and give lectures in his specialty at the post-graduate level.

A major objective of the appointment is to encourage close contact between the present staff and research workers in the Department and an organic chemist of wide University research experience.

The total remuneration, for the 6-month period, will be \$A9,500. There is some possibility that the position could be extended beyond 6 months but this will not be known until later in 1979. The appointment may be held concurrently with study or sabbatical leave from the appointee's own University.

Further information and application forms are available from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF. Applications close on June 8, 1979. 529(A)

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Tropical Hardwoods Research Project — A Forester/Plant Physiologist/Biometrician

To join a team working on the propagation and improvement of West African timber trees, particularly *Triplochiton Scleroxylon*. The appointee will be located in the Forest Research Institute and will work in liaison with the staff there and with others at the Institute of Terrestrial Ecology, Edinburgh.

Applicants should have a good honours degree in forestry and/or botany; at least 5 years post-graduate experience, with evidence of involvement in designing, managing and analysing field and laboratory experiments; an appreciation of the physiological processes affecting tree form. Special knowledge of biometrics/statistics will be an advantage.

Appointment 3 years. (2 tours of 18 months each). Salary (U.K. taxable) in range £8,100—£9,350 p.a., plus a variable tax-free overseas allowance currently in range £4,095—£8,685 p.a. (Ref. 329 X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:—

Sandler, Consultant Chemical Pathologist, Bernhard Baron Memorial Research Laboratories, Queen Charlotte's Maternity Hospital, Goldhawk Road, London W6 0XG. 572(A)

ROYAL GREENWICH OBSERVATORY

HEAD OF ASTROPHYSICS AND ASTROMETRY DIVISION

SENIOR PRINCIPAL SCIENTIFIC OFFICER

There is a vacancy for a senior research astronomer of high ability and wide interests to head the newly-created Astrophysics and Astrometry Division.

The Post

The person appointed will be required to manage and co-ordinate the research activities of scientific staff working in the fields of astrophysics and astrometry, and to develop a coherent research strategy appropriate to the primary role of the Observatory as a provider and operator of telescopes, instruments and measuring machines for use by all UK scientists engaged in ground-based optical astronomy. He/she will be expected to ensure that the Division contributes (in collaboration with University users) to the definition, design, operation and management of such national facilities. The main project now being undertaken is the procurement and subsequent operation of the proposed Northern Hemisphere Observatory in the Canary Islands. Initially, the Division will contain about 30 permanent staff, including at least 7 post-doctoral research astronomers, and 5 or 6 Research Fellows on short-term contracts. Observing is carried out on UK and overseas telescopes.

Qualifications/Experience

The person appointed is likely to be an energetic astronomer with an international reputation for collaborative research in ground-based optical astrophysics or astrometry. He or she should have wide interests and a thorough understanding of contemporary astrophysics. He/she should also have demonstrated ability for leadership of groups with diverse interests.

Salary

On a scale £10,043 to £10,671 to £11,300, subject to review. Non-contributory pension scheme.

Application forms and further information available from Mr T. A. Treglown, Personnel Section, Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, East Sussex BN27 1RP. Closing date for applications June 1, 1979.

534(A)

Anglian Water Authority

Assistant Chemist

Cambridge

Post Ref. R2S15 Grade 4 £4,179—£4,476 p.a.
(including supplements)

Application forms for the above post may be obtained from the Divisional Scientist. The successful applicant will work in the Divisional Laboratory, which is well equipped with modern instrumental and automatic methods of analysis and handles some 10,000 samples per annum from all parts of the water cycle. A degree or equivalent in Chemistry is essential and practical experience in instrumental, classical and automatic monitoring methods of water analysis is desirable.

NJC Conditions of Employment for the Water Service are applicable and the closing date for receipt of applications is Monday, May 14, 1979.

GREAT OUSE RIVER DIVISION

Great Ouse House, Clarendon Road, Cambridge, CB2 2BL
Tel.: (0223) 61561 (Miss Hobbs)

MRC

Medical Research Council

National Institute for Medical Research Computing Laboratory

The Medical Research Council invites applications from suitably qualified candidates with wide experience of computer techniques for the appointment of Head of the Computing Laboratory. The Computing Laboratory, which will be moving into a new building at the end of this year, manages two time shared systems (DEC 2040 and HP 3000) for the Institute and is concerned with developing systems for real time and batch processing.

The Laboratory at present serves the Institute (staff about 600) and some smaller institutions in the London area; the off-site work is likely to increase. Provision has also been made for coupling into a Universities Computer network.

The salary will be within the range for the Council's Senior or Special Appointments grades, which is equivalent to the universities' range for Reader or Professor, plus £502 p.a. London Allowance and superannuation provision.

Applications, giving the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, from whom further details may be obtained. Closing date for applications 15th June 1979.

506(A)

The Research Division of Synthelabo, an internationally recognised pharmaceutical industry located in Paris requires a

CARDIOVASCULAR PHARMACOLOGIST

to join its Department of Biology. For this position we require a candidate for performing work on conscious animals.

The successful candidate should have relevant practical experience and know basic surgical procedures to instrument animals for cardiovascular parameter measurements.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent direct to 'Nature' who will forward.

W78(A)

UNIVERSITY OF SYDNEY CHAIR OF PHARMACEUTICS

Applications are invited for the Chair of Pharmaceutics within the Department of Pharmacy.

Salary will be at the rate of \$A33,061 p.a.

A statement of Conditions of Appointment and Information for Candidates may be obtained from the Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on June 30, 1979. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

523(A)

NMR SPECTROSCOPIST OCTOBER 1, 1979

Ph.D. Physical Science or Graduate degree in engineering. NMR background essential, experience in electronics or chemistry desired. Duties include design, construction, testing of NMR equipment, some instrument operation. \$18,500 or more depending upon qualifications. Closing date: August 1, 1979. Send curriculum vitae and three letters of recommendation to: Dr Stephen E. Ulrich, School of Chemical Sciences, University of Illinois, Urbana, Illinois 61801. An equal opportunity/affirmative action employer.

W83(A)

CHELSEA COLLEGE University of London LECTURER IN CHEMISTRY

Applications are invited for a post of LECTURER in CHEMISTRY which has arisen from a resignation in the Department of Chemistry.

Candidates must have good academic qualifications and a special interest in some aspects of ANALYTICAL CHEMISTRY. Industrial and/or teaching experience at the tertiary level would be an advantage.

Salary scale: £4,385 to £8,256 p.a. (under review) inclusive of £50 London Allowance.

The appointment will commence in September 1979 or as soon after as possible. Application forms and further particulars from the Personnel Officer, Chelsea College, Friese Greene House, Chelsea Manor Street, London SW3 3TW.

Closing date: May 18, 1979.

524(A)

MEDICAL RESEARCH COUNCIL Radiobiology Unit, Harwell TECHNICIAN FOR CELL MUTATION GROUP

The Cell Mutation Group at Harwell is studying the biochemistry and genetics of mutants of cultured mammalian cells induced by ionising radiation. A Technician, preferably with experience in cell culture techniques and/or biochemistry is required for this work.

Qualifications for a technician are H.N.C. or equivalent and salary will be in the scale £3,261 to £4,680. Assisted transport and modern hostel accommodation are available. Applications, giving full personal details including the names of two referees, should be addressed to the Administrator, M.R.C. Radiobiology Unit, Harwell, Didcot, OXON OX11 0RD.

507(A)

THE QUEEN'S
UNIVERSITY
OF BELFAST
DEPARTMENT OF
BIOCHEMISTRY
POSTDOCTORAL

RESEARCH ASSISTANTS

Research Assistant (preferably 4th Ph.D.) required in the Biochemistry Department to investigate the immunoglobins and viral antibodies in sera from psychiatric patients. Experience in virology and/or enzyme immunoassay techniques would be an advantage. Salary scale £3,384 to £3,885 with 1.3.3 Curriculum vitae with the names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast, Belfast, BT7 1NN, Northern Ireland.

RESEARCH TECHNICIAN

Required to assist with a project concerned with the investigation of immunoglobins and viral antibodies in psychiatric patients. Experience in the use of tissue culture for growth of viruses would be an advantage although not essential. Salary scale (Grade 5) £3,474 to £4,056. Application forms obtainable from the Personnel Office, address as above.

The appointments will be from August 1, 1979 (or as soon thereafter) and will be for one year in the first instance, with a possible extension of a further one to two years. 544(A)

THAMES POLYTECHNIC
SCHOOL OF MATERIALS
SCIENCE AND PHYSICS
X-RAY AND NUCLEAR
LABORATORY TECHNICIAN
(Grade 5)

Applications are invited for a Technician for the X-ray and nuclear laboratories who will be required to operate X-ray equipment, handle radioactive sources and be responsible for keeping exposure records. Candidates should have a recognised apprenticeship or H.N.D./H.N.C. qualification and at least eight years' relevant experience.

Salary scale: £3,474 to £4,011 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by May 15, 1979.

555(A)

THE QUEEN'S
UNIVERSITY
OF BELFAST
RESEARCH ASSISTANTS
DEPARTMENTS OF
INDUSTRIAL CHEMISTRY
AND ZOOLOGY

Applications are invited for two research assistantships (Chemist and Zoologist) related to the utilisation of mollusc resources. The designated areas of research are structure and properties of mussel flesh, and the ecology of mussel growth in particular geographic areas respectively. The appointments are supported by a Wolfson Foundation Grant. Each is tenable for three years and the successful applicants may register for research degrees. Initial salaries are in the range £2,640 to £3,400. Applicants should possess (or expect to attain in 1979) a good honours degree in the appropriate field.

Applications with curriculum vitae and the names and addresses of two referees to the Personnel Officer, Queen's University, Belfast from whom further information can be obtained. Closing date: June 30, 1979. 545(A)

CARDIOVASCULAR RESEARCH

Pfizer Research in the U.K., which is part of an integrated international organisation, is located at Sandwich on the Kent Coast. Here in modern, well-equipped facilities, about 600 scientists and supporting staff are engaged in the discovery and development of novel compounds for use in human and veterinary medicine.

We now require an additional innovative pharmacologist to join the department of Developmental Biology, and are looking for a person with post-doctoral experience in cardiovascular research, and preferably in conscious animal work.

The appointment will involve the testing, detailed evaluation and development of compounds as potential antihypertensive agents. The emphasis will be on work with potential candidates for development as drugs and will involve close collaboration with biologists in our discovery biology department.

The man or woman appointed will carry considerable responsibility for planning and supervising the work of a team of some four people. The starting salary will reflect qualifications and experience and there is a good bonus potential. Pension, salary continuance and death benefit schemes are in operation and there is generous assistance with relocation expenses. Flexible hours are worked and the social/recreational facilities are first class.

Applications, which will be treated in confidence, giving details of qualifications, experience, age etc., should be sent to:- D. W. Sells, Pfizer Central Research, Sandwich, Kent.

565(A)

THE UNIVERSITY OF
THE WEST INDIES
TRINIDAD

Applications are invited for a post of
PROFESSOR/
SENIOR LECTURER

in the DEPARTMENT OF AGRICULTURAL ECONOMICS AND FARM MANAGEMENT IN THE FACULTY OF AGRICULTURE, preferably with interest in Quantitative Analysis and/or Agricultural Development. Interest in other areas of Agricultural Economics will be considered. Salary Scale 1977/78 (Under Review): Professor: TT\$36,729 to TT\$45,480 p.a.; Senior Lecturer: TT\$25,827 to TT\$35,901 p.a. (£1 sterling=TT\$4.96). F.S.S.U. Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 20% of pensionable salary. Family passages. Study and Travel Grant. Detailed application (2 copies) together with curriculum vitae and naming three referees to Secretary, U.W.I., St Augustine, Trinidad, as soon as possible. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 517(A)

UNIVERSITY OF LONDON
KING'S COLLEGE
DEPARTMENT OF CHEMISTRY
LECTURESHIPS
IN CHEMISTRY

Applications are invited for two Lectureships, tenable from October 1, 1979 (or from a date to be agreed). Applicants should have an interest in either synthetic organic chemistry or in experimental physical organic chemistry/solution kinetics.

Current salary scale £3,883 to £7,754 p.a. (under review) plus £502 p.a. London Allowance. Universities Superannuation Scheme.

Further information and application forms from the Assistant Registrar, King's College, Strand, London WC2R 2LS, to whom applications (in triplicate) naming two referees should be sent, to arrive by June 11, 1979. 532(A)

UNIVERSITY OF BENIN Nigeria

Vacancies exist in the underlisted departments. Posts range from the level of Assistant Lecturer, for which the minimum qualification is a Second Class Honours (Upper Division) with adequate teaching or research experience, to the level (in some departments only) of Professor, for which higher academic qualifications and relevant University experience will be sought.

Departments of Biological Sciences; Biochemistry; Chemistry; Geology; Mathematics; Physics and Optometry; Civil Engineering; Chemical and Petroleum Engineering; Electrical and Electronic Engineering; Mechanical Engineering; Production Technology and Industrial Engineering; Obstetrics and Gynaecology; Medicine; Radiology; Surgery; Mental Health; Child Health; Community Health; Pathology; Physiology; Pharmaceutics and Pharmaceutical Technology; Pharmaceutical Chemistry and Pharmacognosy; Pharmaceutical Microbiology; Pharmacology; Periodontics; Restorative Dentistry; Preventive Dentistry; Oral Surgery

Salaries

Professor/Director	N 11,288 — N 12,428
Associate Professor	N 9,996 — N 11,028
Senior Lecturer	N 7,784 — N 8,724
Senior Research Fellow	N 7,104 — N 7,752
Lecturer Grade I	N 5,480 — N 6,432
Lecturer Grade II	N 4,368 — N 5,340
Research Fellow	
Assistant Lecturer	

N.B. N1 = approx. 0.78p, subject to exchange rates

Applications. For further details of the posts, specific qualification requirements and the method of application, please write to: Principal Assistant Secretary, Nigerian Universities Office, 180 Tottenham Court Road, London W1 9LE.

Closing Date: 11 May 1979.

583(A)

SOUTH OF SCOTLAND ELECTRICITY BOARD

HUNTERSTON POWER STATION

HEALTH
PHYSICS
ASSISTANT

Applications are invited for the post of Health Physics Assistant at Hunterston 'A' and 'B' Nuclear Power Stations. The Health Physics Department provides a comprehensive radiological protection service and Health Physics Assistants are concerned with the supervision of a personnel dosimetry section, environmental surveys and technical investigations on both 'A' and 'B' Stations.

The successful applicant will be appointed at Third Engineer Grade and given the opportunity to gain a full knowledge of other Health Physics activities with a view to promotion within the department.

Applicants should have a degree or equivalent in Physics or an associated subject; health physics experience is not essential and training will be given.

Salary, which is currently under review and includes responsibility and productivity payments, will be within the range £4,231 to £6,215 per annum (NJB Third Engineer Grade).

Applications (quoting reference number 43/G83/79) should be submitted on the standard form obtainable from and returnable to the Manager, Hunterston Power Station, West Kilbride, Ayrshire, KA23 9QJ, not later than 17th May, 1979. 574(A)

A position is available in the Department of Biochemistry, University of Alberta, Edmonton, T6G 2H7, beginning in the fall of 1979. Applicants should have a good background in DNA metabolism and DNA-drug interactions, both at the graduate and postdoctoral level. A strong background in physicochemical techniques is required for current studies on multistranded nucleic acids and their possible biological roles. Only Canadian Citizens may apply for this position. Please apply to Dr A. R. Morgan at the above address. W73(A)

RESEARCH CHEMIST

BREWING

SALARY RANGE £4,000 TO £5,500

A vacancy exists for an Experimental Officer in the Chemistry Section of the Brewing Research Foundation. The successful applicant will assist in the determination of better ways to utilise the raw materials employed in brewing. This will involve the isolation and characterisation of compounds which are of importance in beer flavour. The position would suit a chemist with a sound theoretical background in organic chemistry together with knowledge of modern instrumental techniques.

Candidates expecting to graduate this summer are invited to apply as also are graduates with relevant industrial experience.

Appointments will be made within the salary range £4,041 to £4,964 to £5,584. Conditions of employment are in keeping with a progressive organisation and include pension/life assurance schemes, social facilities and four weeks annual holiday.

Applications, including a curriculum vitae, should be sent to The Administrative Manager, Brewing Research Foundation, Lyttel Hall, Nutfield, Redhill, Surrey RH1 4HY, to arrive not later than June 1, 1979. 575(A)

LOUGHBOROUGH
UNIVERSITY
OF TECHNOLOGY
LECTURER IN PHYSICS

The Department of Physics has a temporary lecturer post available for one academic year from September 1, 1979 to July 31, 1980. It provides an opportunity for a younger physicist to obtain experience in a university. The person appointed would be expected to lecture to honours degree students and join in one of the research groups.

Salary is within scale £3,883 to £7,754 (under review).

Application forms and further particulars from Paul Johnson, Establishment Officer, Reference 79/15PH, Loughborough, Leicestershire. 511(A)

GLOBAL TECTONICS

The California Institute of Technology is seeking to create a professional position in the general area of global tectonics. Applications are invited for either a junior appointment, at the Assistant Professor level, or a more senior tenure appointment. The areas of specialisation preferred include mantle dynamics, theory and driving mechanism of plate tectonics, global geophysics, and internal fluid dynamics of the earth and planets.

Please send résumé, publications, and names of three references, to Barclay Kamb, Chairman, Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California, 91125. An equal opportunity employer. W84(A)

ST THOMAS'S HOSPITAL
MEDICAL SCHOOL

(University of London)

London SE1 7EH

DEPARTMENT OF CHEMICAL
PATHOLOGY AND
METABOLIC DISORDERS

has vacancy for

MEDICAL LABORATORY
SCIENTIFIC OFFICER

Appointment for one year in the first instance, with possibility of renewal. The successful applicant will assist in the Department's lipid research programme, involving isolation and quantification of human plasma lipoproteins, previous similar experience not essential. Applications with reference to Professor B. Lewis, above address. 594(A)

POSTDOCTORAL RESEARCH
ASSOCIATE POSITION

starting July, 1979, available for Ph.D. with an interest in studying the immunology of pulmonary fibrosis. Applicants must have a strong background in cellular immunology and experience in B and T cell biological assays and enumeration techniques. The Associate will function as part of an ongoing interdisciplinary programme in pulmonary research associated with the Vermont Pulmonary Specialised Centre of Research (SCOR). The individual will have an opportunity to interact with biochemists, pharmacologists, physiologists, and cell biologists at the University of Vermont, as well as physicians in pulmonary medicine at the Medical Centre Hospital of Vermont. Applicants should forward a current curriculum vitae and three letters of reference to Dr Beth Hart, Department of Biochemistry, Given Medical Building, University of Vermont, Burlington, Vermont, 05405, by June 1, 1979. W77(A)

JUNIOR
MEDICAL LABORATORY
SCIENTIFIC OFFICER

required in Host Defence Unit to assist in the investigation of resistance to infection in animals and man. Ideal post for school leaver wishing to make a career in Medical Laboratory Sciences. Applicants should have five 'O' Levels including two relevant sciences. Day Release granted for O.N.C./H.N.C. studies. Apply giving age and qualifications to The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP and quoting ref. 4DU2. 560(A)

UNIVERSITY OF LONDON
WELLCOME CHAIR OF
PHARMACOLOGY AT THE
SCHOOL OF PHARMACY

Applications are invited by Senate for the Wellcome Chair of Pharmacology tenable at The School of Pharmacy. The successful candidate will be Head of the Pharmacology Department in the School and take up his position as soon as possible after September 1, 1979, when the becomes vacant.

Applications (10 copies) should be received by the Academic Registrar (N), University of London, M Street, London WC1E 7HU, from whom further particulars should be obtained. Closing date May 1979. 520(A)

UNIVERSITY OF TORONTO
DEPARTMENT OF
MEDICAL BIOPHYSICS
POSTDOCTORAL POSITION
IN CHEMICAL
CARCINOGENESIS

is available immediately for research on mechanism of action of nitrosamines. Experience in enzymology, drug metabolism desirable. Salary \$12,050 to \$13,350 per annum. See curriculum vitae and references to: Michael C. Archer, Department of Medical Biophysics, University of Toronto, 500 Sherbourne Street, Toronto, Canada M4X 1K9. W75(A)

BIRZEIT UNIVERSITY

An independent Arab University, the Israeli-occupied West Bank, Jordan has the following faculty openings for the academic year 1979/1980: **Biology-Biochemistry, Chemist (Physical, Inorganic, Organic), Mathematics (Algebra, Analysis, Mathematical Statistics), Physics (Experimental and Theoretical).**

English is the basic language of instruction and candidates should have a Ph.D. preferably or a master degree with experience.

Starting annual salary for Ph.D. 2,700 Jordanian Dinars (current exchange rate 1 J.D. equals about £1.7). Optional summer teaching extra. Fringe benefits include: Relocation allowance (15% of salary). Transportation also provided.

All applications should be addressed to: Dean of the Faculty of Science, Birzeit University, Birzeit, West Bank, via-Israel. W71(A)

THE HOSPITAL FOR
SICK CHILDREN
AND
UNIVERSITY OF TORONTO
RESEARCH
PHARMACOLOGIST

The Hospital for Sick Children Research Institute invites applications for the position of Scientist in the Division of Clinical Pharmacology. Ph.D. or equivalent in pharmacology or related field with at least 2-5 years postdoctoral experience required. Emphasis on developmental biochemical pharmacology preferred. University rank and salary negotiable. Send letter of application, curriculum vitae and three reference letters to Dr S. M. MacLeod, Division of Clinical Pharmacology, Hospital for Sick Children, 555 University Avenue, Toronto, Ontario, Canada M5G 1X8. W74(A)

UNIVERSITY OF
LONDON
RESEARCH ASSISTANT

Graduate research assistant preferably with research experience in physiological psychology or psychopharmacology required as soon as possible for a project on brain control of body weight and motivation in rats, funded for one year in the first instance. Salary and superannuation on University scale. Apply with curriculum vitae and names of referees to Dr. L. J. Herberg, Experimental Psychology Laboratory, Institute of Neurology, National Hospital, Queen Square, London WC1. 525(A)

Liverpool Area Health Authority (T)

Regional Cardiac Centre, Sefton General Hospital,
Smithdown Road, Liverpool L15 2HE

BIOCHEMIST (Basic Grade)

Applications are invited for the post of Biochemist (Basic Grade) in the Centre Laboratory, which is concerned with biochemical aspects of heart disease.

Whitley Council conditions of pay and service apply. Newly qualified graduates will be considered.

Application forms obtainable from the Sector Administrator,
Sefton General Hospital, Smithdown Road, Liverpool L15 2HE.
Closing Date: 15th June 1979. 590(A)

RESEARCH OFFICER

Required at our Mill Hill Laboratories NW7 to assist with research into some aspects of the control of gene expression during development. This involves the utilisation of recombinant molecules containing segments of eukaryotic DNA to investigate the structure and transcription of developmentally regulated genes.

H.N.C. degree plus two years research experience essential. Some experience of biochemical techniques useful.

Salary £3,936 to £5,256. For further information and application form write or telephone Miss P. Maddox at the Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2, on 242 0200 ext. 305. 585(A)

UNIVERSITY OF EDINBURGH POSTDOCTORAL RESEARCH FELLOW

Applications are invited for this S.R.C. financed post to work on theoretical aspects of inelastic collisions between atoms and molecules. Close liaison is maintained with the Molecular Beams and the Spectroscopy Groups in the Physics and Chemistry Departments, and a background in either of these fields, or in theoretical chemistry is desirable. The work will be under the supervision of Dr K. P. Lawley.

Applications with a curriculum vitae and the names of two referees should be sent to Dr Lawley at the Department of Chemistry, West Mains Road, Edinburgh. Please quote Reference 5019.

549(A)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF PHYSICS Postdoctoral Research Associate

Applications are invited for the position of Research Associate to work with Drs D. J. Meredith and J. K. Wigmore on a study of phonon echoes and non-linear acoustic interactions in solids. Candidates should have completed a Ph.D. in solid state physics, and particular experience with low temperatures, microwaves, or lattice dynamics would be advantageous but not essential. The appointment would be for two years beginning October 1, 1979 at a salary in the range £3,883 to £5,604 (depending on experience).

Further particulars may be obtained (quoting reference L129/B) from the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW, to whom applications (6 copies) naming three referees, should be sent not later than May 14, 1979. 591(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH LECTURER IN ANIMAL SCIENCE

Required—Lecturer in Animal Science in the Department of Agriculture tenable from October 1, 1979.

The successful applicant will participate in the teaching of undergraduate and postgraduate courses in Animal Science and Animal Health. Postgraduate qualifications or veterinary experience are highly desirable. Salary on the Scale for Lecturers £3,883 to £7,754 per annum (under review).

Application forms and further particulars from The Registrar, The University College of Wales, Aberystwyth SY23 2AX. Closing date for applications May 31, 1979. 504(A)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF PHYSICS POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the position of Research Associate to work with Drs D. J. Meredith and J. K. Wigmore on a study of phonon echoes and non-linear acoustic interactions in solids. Candidates should have completed a Ph.D. in solid state physics, and particular experience with low temperatures, microwaves, or lattice dynamics would be advantageous but not essential. The appointment would be for two years beginning October 1, 1979 at a salary in the range £3,883 to £5,604 (depending on experience).

Further particulars may be obtained (quoting reference L129/B) from the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW, to whom applications (6 copies) naming three referees, should be sent not later than May 14, 1979. 505(A)

UNIVERSITY OF MANCHESTER LECTURESHIP IN PHARMACY

Applications are invited from honours graduates in Pharmacy, who should preferably have a higher degree, for a lectureship in the Pharmaceutics area. Applicants should have an interest in physical pharmacy or pharmaceutical technology. Excellent facilities are available for research.

Salary range: £3,883 to £7,754 per annum. Superannuation.

Particulars and application forms (returnable by May 31) from the Registrar, The University, Manchester M13 9PL. Quote Ref. 84/79/N. 509(A)

Scientific Officer/ Higher Scientific Officer £2,839 – £5,448

Applications are invited for a pensionable post in the Field Botany Division of the Department of Agriculture situated at Newforge Lane, Belfast.

The successful candidate will carry out research in the field and under controlled environmental conditions aimed at increasing productivity and utilisation of pasture in hill land in Northern Ireland. The successful candidate may also be required to undertake lecturing duties in the Faculty of Agriculture and Food Science, Queen's University, Belfast.

Higher Scientific Officer

Under 30 years of age at 31 December 1979 and possess a first or second class Honours Degree in Agricultural Botany, Agriculture or Botany and at least 2 years' relevant post-graduate experience.

Scientific Officer

Under 27 years of age at 31 December 1979 with an Honours Degree as above.

A clean driving licence is essential.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including the level of academic attainment and relevant experience) to be best qualified.

Salary Scales

Higher Scientific Officer — £4,101-£5,448
Scientific Officer — £2,839-£4,415

(the salary scales will be subject to review from 1 April 1979).

Grading and starting salary will be related to qualifications and experience.

There are prospects of promotion to Senior Scientific Officer (£5,514-£6,898) and to Principal Scientific Officer (£6,609-£8,461).

Please write or telephone for an application form quoting job reference SB 198/79/NN to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 22 May 1979. 510(A)

**NORTHERN IRELAND
CIVIL SERVICE**

Liverpool Area Health Authority (Teaching)

ROYAL LIVERPOOL HOSPITAL
PRESCOT STREET, LIVERPOOL L7 8XW

Clinical Biochemist (Basic Grade)

Applications are invited for the above post in the Department of Chemical Pathology and Metabolic Medicine at the Royal Liverpool Hospital.

The Department carries out the full range of routine, specialised and advanced assays for this new teaching hospital and is recognised for the M.R.C. Path and M.C.B. There are excellent opportunities of working for a higher degree.

Application forms are available from the Area Personnel Department, Liverpool Area Health Authority (T), Orleans House, Edmund Street, Liverpool L3 9NG.

Closing date: 25th May, 1979.

543(A)

UNIVERSITY OF ALBERTA

Applications are invited from graduates with a good background in biochemistry or chemistry to undertake fundamental research on proteoglycans or glycoproteins leading to an M.Sc. or Ph.D. degree. Well equipped laboratories include automated amino acid sequencer and amino acid and carbohydrate analysers. Stipends are available for suitably qualified persons and travel allowances may be provided.

Enquiries should be sent to Dr C. H. Pearson, Department of Oral Biology, Dentistry-Pharmacy Centre, University of Alberta, Edmonton, Alberta T6G 2N8, Canada. W76(A)

UNIVERSITY OF GLASGOW
ADMINISTRATIVEASSISTANT
INSTITUTE OF VIROLOGY

Applications are invited from university graduates for the post of Administrative Assistant in the Institute of Virology. Salary will be within the Range £3,384 to £5,604 (interim) with placing according to qualifications and experience. A degree in science, preferably biological, is desirable but not essential.

Further particulars may be had from the Secretary of the University Court (Room 18), University of Glasgow Glasgow G12 8QQ, with whom applications (eight copies) giving the names and addresses of three referees should be lodged on or before May 18, 1979.

In reply please quote Ref. No. 4434 M. 548(A)

STUDENTSHIPS

UNIVERSITY OF LONDON
MEDICAL
RESEARCH COUNCIL

Applications are invited for a postgraduate studentship, associated jointly with the MRC Cell Biophysics Unit, King's College, and the Department of Clinical Haematology, University College Hospital Medical School, under the MRC Partnership Award scheme. The research will be concerned with the mechanisms by which the cytoskeletal proteins of the red cell control its shape and the properties of the membrane, and in particular with the nature of the anomalies in functionally abnormal cells from subjects with haemolytic and other inherited red cell disorders. Applications, giving the names and addresses of two referees, should be sent to Professor E. R. Huehns, Department of Clinical Haematology, University College Hospital Medical School, University Street, London WC1. 570(F)

MINISTRY OF
AGRICULTURE,
FISHERIES AND FOOD
POSTGRADUATE
RESEARCH STUDENTSHIPS

The Ministry of Agriculture, Fisheries and Food are offering to suitable candidates two Studentships tenable at the School of Agriculture, Aberdeen.

The areas of research are:

1. Evaluation of practices aimed at reducing levels of pig mortality. (Dr P. R. English).
2. Nutrient requirements of bulls and castrates treated with anabolic compounds. (Dr H. Galbraith).

Candidates should possess at least an upper second class Honours degree in Agriculture or allied subjects, or be completing their Honours degree in June 1979. They must be normally resident in England or Wales and be studying at a University in the United Kingdom.

The value of the M.A.F.F. award in 1979 will normally be £1,610.

Interested applicants should write immediately to Professor G. A. Lodge, School of Agriculture, University of Aberdeen, stating for which research topic they wish to be nominated and giving the names of two persons to whom reference can be made.

586(F)

MEAT
RESEARCH INSTITUTE
SCIENTIFIC OFFICER

Applications are invited for a Scientific Officer post in the Division of Meat Structure involving work on proteins of the contractile apparatus of muscle.

Experience in protein chemistry and/or electron microscopy would be an advantage.

Qualifications: Honours degree or equivalent or an ordinary degree with relevant experience.

Salary: Scientific Officer Grade £2,839 to £4,415 (starting salary depending on qualifications and experience).

Non Contributory Pension Scheme. Closing date for return of application forms May 11, 1979.

Application forms from: The Personnel Officer, Meat Research Institute, Langford, Bristol BS18 7DY. 531(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF GEOLOGY
ROCK-SECTION
TECHNICIAN WANTED

Applications are invited for a person to take charge of the rock-cutting workshop. The appointed person will have had several years experience in this type of work together with some educational qualifications.

The position carries a salary of £3,474 to £4,056 per annum (Grade 5) (scale review). Applications, including the names of two referees, to: The Superintendent, Department of Geology, Queens Building, University Walk, Bristol BS8 1TR. To be received within two weeks of this advertisement appearing. 584(A)

APPLIED ECOLOGY
RESEARCH GROUP
REDLAND PURLE
RESEARCH
STUDENTSHIP

Applications are invited from candidates with a good Honours degree in Zoology or Biology for a research studentship concerned with a study of invertebrate communities in freshwater habitats adjacent to a landfill site.

The project which will involve close collaboration with Redland Purle Ltd, the industrial sponsors, will be based within the Applied Ecology Research Group of the Polytechnic of Central London, and will be at standard research council rates. The successful candidate will be registered for a higher degree with the C.N.A.A. A full current driving licence is essential.

Salary: £3,087 to £3,261 inclusive of London Allowance.

Application form and further details from the Establishment Officer, P.C.L., 309 Regent Street, London W1R 8AL (Tel 01-580 2020, Ext 212) 550(F)

A.R.C. RESEARCH
STUDENTSHIP 1979

Applications are invited for an Agricultural Research Council Studentship to join a group working on the structure of foot-and-mouth disease virus RNA and the biochemistry of virus mutants as they relate to the function of the RNA. The Studentship will be tenable for up to 3 years from October 1979 and the successful candidate will be expected to read for a higher degree. Applicants should possess, or expect to obtain, a good honours degree in a Molecular Biological subject.

Application forms and further particulars may be obtained from the Secretary, The Animal Virus Research Institute, Pirbright, Woking Surrey, GU24 0NF, applications should be received by May 14, 1979. 571(F)

THE OPEN
UNIVERSITY
Physics
Department
Research
Studentships

Applications are invited from graduates interested in pursuing research towards the degrees of B.Phil, M.Phil, or Ph.D. in the following areas: biomagnetism (SQUID magnetometry); nanosecond molecular spectroscopy; optical properties of semiconductors; solar energy (interseasonal storage); triboluminescence. In each area the student would work under one or more members of the permanent academic staff. A small number of both the normal SRC grants and internal OU grants may be available to qualified candidates. Further particulars may be obtained from Dr. S. J. Swinbenby, Faculty of Science, The Open University, Walton Hall, Milton Keynes, MK7 6AA.

Please quote reference PY 3 Closing date for applications 10th May 519(F)

AGRICULTURAL
RESEARCH COUNCIL
STUDENTSHIP

Applications are invited for an A.R.C. postgraduate studentship tenable at the Meat Research Institute for research into the viscoelastic properties of semi-solid foodstuffs.

The work will involve a study of the transmission of mechanical pulses through foods and computer analysis of transient stresses generated with an Instron materials tester.

The project is expected to form the basis for a Ph.D. thesis in the University of Bristol and the appointment will commence in October 1979.

Candidates should possess a First or Upper Second Class degree in Physics or a related subject.

Further particulars of the award and allowances together with Application Forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol BS18 7DY. 579(F)

UNIVERSITY OF
ABERDEEN
DEPARTMENT OF THERAPEUTICS
AND CLINICAL PHARMACOLOGY
AND DEPARTMENT OF
PHARMACOLOGY

Applications are invited for a Ph.D. studentship tenable in the above departments from October 1979.

The project will involve a comparison of the pharmacokinetic and pharmacodynamic effects of drugs used in the treatment of hypertension and/or cancer chemotherapy.

Applicants should have or expect to gain a good honours degree in Pharmacology or Biochemistry. A brief curriculum vitae and the names of two academic referees should be submitted within two weeks of the appearance of this advertisement to: Dr H. E. Barber, Department of Pharmacology, University Medical Buildings, Foresterhill, Aberdeen AB9 2ZD. 587(F)

UNIVERSITY OF LONDON
KING'S COLLEGE
DEPARTMENT OF CHEMISTRY
RESEARCH
STUDENTSHIPS

Applications are invited for College Tutorial and SRC (including CASE) postgraduate studentships in all areas of Chemistry. Applicants should hold or expect to obtain a First or Upper Second Class Honours degree from UK universities (or CNAAs) or Grad RIC of equivalent standing.

Further information and application forms from Prof V. Gold, FRSc, King's College, Strand, London WC2R 2LS. 533(F)

AGRICULTURAL
RESEARCH COUNCIL
POULTRY RESEARCH
CENTRE,
KING'S BUILDINGS,
WEST MAINS ROAD,
Edinburgh EH9 3JS, Scotland
NUTRITION
DEPARTMENT
RESEARCH
STUDENTSHIP

Applications are invited for three-year Agricultural Research Council Research Studentship study dietary factors affecting digestion and metabolism of or by poultry. A wide range of rational and physiological techniques are available. Supervision by J. M. McNab from whom full details of the proposed research can be obtained.

The person appointed must be a 1st or upper 2nd honours degree in agricultural science or nutrition and will be expected to apply for registration as a postgraduate student (Ph.D.) at the University of Edinburgh.

Application form and full details from the Assistant Secretary at the above address. 503(F)

UNIVERSITY
OF DUNDEEDepartment of Physiology
M.R.C. POSTGRADUATE
STUDENTSHIP

available from October 1. Applications, with the name of two referees, to Professor O. Peterson, Department of Physiology, The University of Dundee, DD1 4HN before May 10, 552(F)

UNIVERSITY OF LEICESTER
DEPARTMENT OF ZOOLOGY
SCHOOL OF
BIOLOGICAL SCIENCES
POSTGRADUATE
RESEARCH STUDENTS

Applications are invited for a graduate research studentship funded by the Medical Research Council for three years for the study of regulation and determinants of spatial patterns of cellular differentiation in arthropods.

The study would be of particular interest to those with some knowledge and background in Developmental Cell or Neurobiology, although candidates with other qualifications will be considered.

Applicants should send a curriculum vitae and names and addresses of referees to Dr P. M. J. Shelton, Department of Zoology, University of Leicester, Leicester LE1 7RH, as soon as possible. 51

THE ANIMAL VIRUS
RESEARCH INSTITUTE
Pirbright
A.R.C. RESEARCH
STUDENTSHIP 1979

Applications are invited for an Agricultural Research Council Studentship to join a group working on the structure of foot-and-mouth disease virus RNA and the biochemistry of virus mutants as they relate to the function of the RNA. The Studentship will be tenable for up to 3 years from October 1979 and the successful candidate will be expected to read for a higher degree. Applicants should possess, or expect to obtain, a good honours degree in a Molecular Biological subject.

Application forms and further particulars may be obtained from the Secretary, The Animal Virus Research Institute, Pirbright, Woking, Surrey, GU24 0NF, applications should be received by May 14, 1979. 55

UNIVERSITY OF NEWCASTLE UPON TYNE M.R.C. RESEARCH STUDENTSHIP

Applications are invited from good students with honours in a biological science and from students expecting to graduate in 1979 for an M.R.C. research studentship to study myofibrillar generation in muscular dystrophy in 1. The work will involve quantitative techniques of electron microscopy, light microscopy and, possibly, tissue culture, and will be carried out in the Muscular Dystrophy Research Laboratories at Newcastle General Hospital in association with Dr M. J. Lennox. The studentship (value £1,610 per annum) is tenable for three years and a successful candidate will be registered for the degree of Ph.D. Applicants should write to Dr M. J. Lennox, Muscular Dystrophy Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne, enclosing a curriculum vitae and names and addresses of two referees, by May 14, 1979. 460(F)

RESEARCH STUDENTSHIPS

Applications are invited from graduates with honours (or those about to graduate) in a biological science to undertake a 3 year project on the effect of hormones on mammalian heart muscle. (This is a joint project between the National Heart and Royal Free Hospitals and the Nuffield Laboratories of Comparative Medicine, Zoological Society of London.) Candidates should have an interest in pharmacology, electron microscopy and/or cardiac physiology and will be expected to register for a higher degree. Candidates of employment will follow those set out by the Research Councils for Studentships.

Applications accompanied by a full curriculum vitae and the names of two referees should be sent to Mrs J. French, Personnel Department, Royal Free Hospital, Pond Street, London, N.W.3. (Telephone 01-794 0500, Extension 4343) and from whom further particulars may be obtained. Candidates expecting to graduate this summer will be considered. Closing date May 14, 1979. 564(F)

FELLOWSHIPS

UNIVERSITY OF ABERDEEN GEORGINA McROBERT CANCER RESEARCH FELLOWSHIP

Applications are invited for a postdoctoral cancer research fellowship available in one of the departments of Anatomy, Bio-Medical Physics and Bio-Engineering, Therapeutics and Clinical Pharmacology, Pathology, Biochemistry, Bacteriology and Developmental Biology.

Salary within range of £3,883 to £6,555 per annum with appropriate housing. Initial appointment for three years, from October 1979, with possible extension to five.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by May 18, 1979. 558(E)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND CANADA DEPARTMENT OF GEOLOGY A POSTDOCTORAL FELLOWSHIP

is available for a condodont specialist with extensive documented knowledge of Middle Ordovician North Atlantic faunal province condodonts. The successful applicant will participate in an on-going sedimentological and paleoecological study of the Table Head Formation and related rocks in western Newfoundland.

The appointment will be effective September 1, 1979 at a salary of \$12,900 and will be for one year in the first instance.

Applications, including the names and addresses of two referees, should be sent by June 1, 1979 to: Head, Department of Geology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X5. 518(E)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF CHEMISTRY

Several Postdoctoral Research Fellowships will be available from October 1, 1979 for development of new synthetic methods or synthesis of natural products under Professor R. Baker or Professor R. C. Cookson. A fellowship is also available in the Chemical Entomology Unit for a chemist with biological interests. Salary within range £4,133 to £4,382 (under review) plus superannuation.

Applications, including brief curriculum vitae and names of at least two referees, should be sent to Professor R. Baker or Professor R. C. Cookson, Chemistry Department, Southampton University, Southampton SO9 5NH. 566(E)

UNIVERSITY OF ABERDEEN DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a S.R.C. fellowship to work with Professor R. H. Thomson and Dr A. R. Forrester on the generation and reactions of atomic nitrogen in solution. Applicants with experience in synthetic and/or free radical chemistry will be preferred.

The appointment is for two years beginning July 1, 1979 or as soon as possible thereafter.

Commencing salary within Range 1A, £3,883 to £4,382 per annum (under review) with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by May 25, 1979. 569(E)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF PHYSICS RESEARCH FELLOWSHIPS IN CRYOGENICS

Applications are invited for Postdoctoral Fellowships to work on the following projects:

1. Heat transfer in the reboiler/condensers of cryogenic plant, using model rigs and a full length test section.
2. Complex convective flow in stratified cryogenic vapours and liquids using Laser Doppler Anemometry.
3. Heat transfer and fluid behaviour of helium at 3,000 r.p.m. for the development of large superconducting machines.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salary in range up to £5,367 plus U.S.S. benefits.

Applications with names of two referees should be sent to Mrs E. C. P. Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH. Please quote reference number 1607/R/N. 441(E)

QUEEN'S UNIVERSITY Kingston, Ontario

Applications are invited for a M.R.C. supported postdoctoral fellowship to work with Dr B. T. Eaton on the study of arbovirus persistence in mosquito cells. The appointment is available for two years and the initial salary is \$12,000 per annum. Prospective or recent Ph.D. graduates should send their curriculum vitae and the names of two referees to Dr Eaton, Department of Microbiology and Immunology, Queen's University, Kingston, Ontario K7L 3N6, Canada. W80(E)

The Queen's University of Belfast POSTDOCTORAL RESEARCH FELLOWSHIP

Pharmacokinetics and
Metabolism of Anticancer
Drugs

The Department of
Biochemistry

This work on drugs used for combination chemotherapy of breast cancer will be carried out in the Action Cancer Unit in collaboration with existing research staff. Techniques used include G.L.C. and radioimmunoassay. The post is tenable until September 30, 1982, on the scale £3,885 to £5,130 per annum, according to age and qualifications.

Further details are available from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland, to whom applications, together with the names and addresses of two referees should be sent. 546(e)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF CHEMISTRY

Applications are invited for a Science Research Council sponsored Postdoctoral Fellowship to work in the field of photoelectron spectroscopy. The work will involve studies of gaseous free radicals and molecular fragments generated by high temperature pyrolysis.

The post will be available from a suitable agreed date for one year in the first instance and is renewable for a second year by mutual agreement. This position should appeal to a chemist or physicist with related experience although this is not essential. Salary commensurate with age and experience, membership of U.S.S. available.

Applications, including a curriculum vitae and the names of two referees should be sent to: Professor N. B. H. Jonathan or Dr J. M. Dyke, Department of Chemistry, The University, Southampton SO9 5NH. Ref. No. N. 567(E)

UNIVERSITY OF ABERDEEN DEPARTMENT OF GEOLOGY AND MINERALOGY POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from suitably qualified organic geochemists or clay mineralogists to work with Dr M. J. Pearson on the correlation of organic matter and clay mineral diagenesis in sediments from the North Sea Basin. The project involves the study of kerogen maturation and hydrocarbon generation during burial in relation to clay mineral transformations as a response to temperature increase and ion concentration in interstitial water.

The post is tenable for three years and is supported by the Natural Environment Research Council.

Salary £4,382 to £4,882 per annum on Research and Analogous Staff Range 1A Scale (under review), with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by May 18, 1979. 557(E)

CONFERENCES

Quekett Microscopical Club Lecture. Dr James Dyson, Sc.D., F.R.S., will speak on 'Interference and Image Shearing Microscopy' at 6.30 p.m. on Tuesday, May 8, at the British Museum (Natural History), Cromwell Road, South Kensington, London SW7 5BD. All Club members and visitors are welcome. 563(C)

ASSISTANTSHIPS

UNIVERSITY OF OXFORD DYSON PERRINS LABORATORY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship supported by the S.R.C. to develop new protecting groups for histidine in peptide synthesis. Previous experience in synthetic organic chemistry is essential, and practical knowledge of peptide, amino-acid or heterocyclic chemistry will be advantageous.

The appointment is for two years, commencing September 1, 1979, or as soon as possible thereafter. The salary will be on the Research Support Grade Scale 1A, initially not higher than £4,382 p.a. (under review), plus U.S.S. benefits.

Applications (one copy), with curriculum vitae and the names and addresses of two referees (overseas applicants should ask referees to write directly to the address below) should be sent as soon as possible and in any case not later than May 31, 1979, to Dr J. H. Jones, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, England, from whom further details may be obtained. 588(P)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR RESEARCH POSTS IN ORGANIC CHEMISTRY

Applications are invited for postdoctoral research assistantships in the College's School of Physical and Molecular Sciences, to work in collaboration with Professor C. J. M. Stirling on measurement of the effect of ring strain on reactivity in organic reactions.

The appointments, to commence on October 1, 1979, or such earlier date as may be arranged, will be for one year in the first instance, with the possibility of extension for a further two years, and will be within the salary range:—£3,883 to £4,382 per annum (under review).

Applications (two copies), giving details of qualifications and research experience, together with the names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd, as soon as possible. 538(P)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited from physicists or astronomers, preferably with postdoctoral research experience, for a

SENIOR RESEARCH ASSISTANTSHIP

to be responsible, with an electronic engineer, for the design of a new experimental facility in high energy gamma-ray astronomy. The experiment will use the atmospheric optical Cerenkov radiation technique at present in use in a large cosmic ray detector array in Utah, U.S.A.

This appointment is tenable for two years from October 1979, and will involve working for a number of short periods overseas, most probably in the U.S.A. (Further details from either Dr K. E. Turver or Dr K. J. Orford. Tel. Durham 64971.)

Initial salary in the range £3,883 to £4,631 per annum (under review) plus superannuation.

Applications (three copies) naming three referees should be sent by May 31, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 540(P)

ASSISTANTSHIPS—cont.

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL
RESEARCH ASSISTANTSHIP
IN PROTEIN
CRYSTALLOGRAPHY

Applications are invited for an S.R.C. funded postdoctoral research assistantship to study the high resolution crystal structure and the substrate and effector binding sites of Pyruvate Kinase.

The appointment is for a period of three years with an initial salary of up to £24,382 per annum (Point 3 on Range 1A of the University scales—scale under review). Applicants should have previous research experience in crystallography.

Applications, including a brief curriculum vitae, research experience and names and addresses of two referees, should be sent to Dr H. Muirhead, Department of Biochemistry, University of Bristol, Bristol BS8 1TD, as soon as possible. 513(P)

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY
RESEARCH ASSISTANT
IN BIOCHEMISTRY

Applications are invited for an S.R.C. funded postgraduate research assistantship. The successful applicant would help with the purification of enzymes, preparation of crystals and data collection in a protein crystallographic laboratory.

The appointment is for a period of three years with an initial salary of £3,384 per annum on Range 1B of the University scales (scale under review).

Preferred qualifications: Degree in Biochemistry or equivalent.

Applications, including a brief curriculum vitae, and names and addresses of two referees should be sent to Dr H. Muirhead, Department of Biochemistry, University of Bristol, Bristol BS8 1TD, as soon as possible. 512(P)

UNIVERSITY OF DURHAM
DEPARTMENT OF
BOTANY

Applications are invited from graduates in Botany, microbiology or bacteriology for a

**POSTDOCTORAL
SENIOR**

RESEARCH ASSISTANTSHIP

tenable for 2½ years from July 1, 1979 or as soon as possible thereafter, on a N.E.R.C. funded investigation into the physiological ecology of blue-green algae/cyanobacteria.

Salary at the appropriate point on Range 1A £3,883 to £6,555 plus superannuation.

Applications (three copies) naming three referees should be sent by May 8, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 539(P)

COURSES

UNIVERSITY OF LEICESTER
DEPARTMENT OF CHEMISTRY
AND SCHOOL OF EDUCATION
Ph.D. IN CHEMISTRY WITH
GRADUATE CERTIFICATE
OF EDUCATION

Applications are invited from persons holding, or expecting to be awarded during 1979, a degree with First or Second Class Honours (Upper division), or equivalent qualifications, in Chemistry, Combined Sciences, Chemical Engineering, Physics, etc., who wish to pursue a 3-year course of research and teacher training.

The course may attract a limited number of Science Research Council quota awards, principally for new graduates, but candidates from industry or teaching may be eligible to apply for awards under other S.R.C. schemes.

For further information and application forms please write to Professor R. D. Peacock, Department of Chemistry, University of Leicester LE1 7RH.

The closing date for applications is May 31, 1979. 515(D)

GRANTS

**N.E.R.C. RESEARCH GRANTS IN GEOPHYSICS
AND PLANETARY PHYSICS**

Research studentships are available in the Department of Geophysics and Planetary Physics in the School of Physics at the University of Newcastle upon Tyne, for work starting in October 1979 and leading to a Ph.D. degree, in the following topics:

A Geophysical Study of Afar, a region of active plate boundaries (Dr R. W. Girdler)

Assessment of the contribution of altered silicates to the palaeomagnetic record (Dr W. O'Reilly)

Magnetic Fabric of Consolidated and Unconsolidated Sediments (Dr D. H. Tarling)

Laboratory Studies of flows in rotating, thermally-stratified fluids (Dr C. W. Titman and Dr P. A. Davies)

Experimental Fluid Dynamics related to topographically generated wind-storms (Dr D. J. Tritton)

Laboratory Experiments related to effect of Mantle Convection on Core Formation (Dr D. J. Tritton)

Laboratory Investigation of Mechanisms responsible for origin of planetary magnetic fields (Dr I. Wilkinson)

For further details, write to Mr J. M. Walmsley, School of Physics, The University, Newcastle upon Tyne NE1 7RU. 536(H)

Pushing back the frontiers of medicine

The new editions of these two highly respected books reveal the dramatic strides taken in the last few years in laboratory diagnosis of infectious disease. Both books include a vast amount of detailed, up-to-date information and reflect current laboratory practices, legal requirements, and the increased demands placed on health laboratories.

Two-volume set \$49.00

Diagnostic Procedures for Viral, Rickettsial and Chlamydial Infections

Fifth Edition

Edwin H. Lennette and Nathalie J. Schmidt, eds.

Recent breakthroughs in knowledge of the herpes viruses, followed by an explosion of research, have brought a new understanding of viral hepatitis, viral gastroenteritis, and Epstein-Barr viral disease. The book contains the latest information in these areas and also on viral immunology - cell mediated immunity, immune complexes, and the relation of immunoglobulin classes to laboratory diagnosis. New chapters on radioimmunoassay and immunoenzymatic techniques have been added and the chapter on fluorescent antibodies expanded. Finally, the new title reflects the increasing recognition of the *chlamydiae* as important disease agents.

Approx. 1000 pages. \$28.00

Diagnostic Procedures for Bacterial, Mycotic and Parasitic Infections

Sixth Edition

Albert Balows and William J. Hausler, Jr., eds.

The discussion of operation and management of laboratories includes a new chapter on the role of the laboratory in epidemiology, nosocomial infections, opportunistic infections, and infection control. New material on bacterial diseases includes cell wall defective organisms and their relation to infection, mycoplasma infections, antibiotic susceptibility testing and immunodiagnostic technics. The mycotic diseases section now covers opportunistic mycotic infections and antifungal susceptibility tests. The section on parasitic diseases has new chapters on malaria, protozoan and helminth infections. The book gives an authoritative discussion of the agent involved in "Legionnaires" disease.

Approx. 1000 pages. \$28.00

Also - an important new book

Quality Assurance Practices for Health Laboratories

Five management and 15 discipline-specific chapters provide guidelines for improving performance of health and environmental laboratories. (1978) 1264 pages. \$40.00

American Public Health Association/1015 18th St. N.W./Washington, D.C. 20036

ORDER FORM

π Into the 1980's with Pitman Bioscience

The Pitman Series in Cellular and Developmental Biology

Editorial Board: J R BRONK, York (Co-ordinating editor); P R BELL, University College, London; J BONNER, California Institute of Technology; W F FRANKE, Deutsche Krebsforschungszentrum Heidelberg; C G KURLAND, Uppsala; C A PASTERNAK, St George's Hospital Medical

School, London; L D PEACHEY, University of Pennsylvania; J P REVEL, California Institute of Technology.

Scope: Studies on the function and development of cells and higher organisms straddling the subdivisions of biology.

The Pitman Series in Neurobiology and Behaviour

Editorial Board: D J McFARLAND, Oxford (Co-ordinating editor); N ADLER, University of Pennsylvania; R D FERNAULD, Oregon; G A HORRIDGE, Australian National University; F HUBER, MPIV, Seewiesen; M KONISHI,

California Institute of Technology; J KREBS, Oxford; H SCHEICH, T H Darmstadt.

Scope: All topics within this very broad field ranging from neurochemistry to behavioral ecology.

The Pitman Series in Environmental and Evolutionary Biology

Scope: Evolutionary science embraces genetic mechanisms, new techniques in systematics, evolutionary palaeontology and phylogenetic theory, and everything between. Environmental biology includes population dynamics, theoretical

ecology, autecology and synecology. Attention will also be directed to the increasingly important common ground between evolutionary and environmental biology.

The Pitman Series in Applied Biology

Scope: All bioscience research that has industrial, commercial or agricultural applications. This will include such areas as biotechnology, biodeterio-

ration, environment, fresh and salt water biology, food science.

Manuscript Submissions

Our aim is to establish a multidisciplinary forum in bioscience by publishing rapidly and worldwide important new research, both pure and applied. When necessary we will publish within four months of receiving the typescript.

Our policies include:

* Rapid publication * Excellent production standards for text and illustrations * Major publicity

* Worldwide dissemination * Generous royalties * Advice and assistance (including financial) with all aspects of planning, writing and illustrating your work.

Patterns of Development in Conidial Fungi

Garry T Cole University of Texas at Austin, and
Robert A Samson Centraalbureau voor
Schimmelcultures, Baarn

This highly illustrated work represents a comprehensive and up-to-date treatment of aspects of conidiogenesis and application of developmental characters to the systematics of deuteromycetous fungi (conidial fungi).

The authors suggest an interesting experimental classification of hyphomycetes (based on micrographs and text) and apply this to the entire group of imperfect fungi.

Cased/1979/276 x 219 mm/240 pp/Illustrated with
over 100 electronmicrographs/0 273 08407 0/
£29.75 non net.
